# Standing for a Century

## 1810 — 1910

LIKE some stalwart giant of the forest, which for a century has withstood the violence of the elements, the **Hartford Fire Insurance Company** has completed its hundredth year of vigorous life. Since 1810 a host of insurance companies have disappeared in the smoke of a fiery century. During that period the **Hartford** paid over One Hundred and Thirty Million Dollars in losses, and yet, as years passed, grew greater and stronger. It stands to-day like the mighty tree, unblemished, sound to the core, and still growing with all the vigor of youth.

A century of success *must* be based on right service. When you buy fire insurance secure the best. It costs no more.

## ENGINEERS—IT'S FREE!

Write to-day for 24-page pamphlet giving 172 questions asked by Examining Board of Steam and Electrical Engineers—questions you must answer before you can get a license. This valuable pamphlet is the index to SPANGENBERG'S STEAM AND ELECTRICAL ENGINEERING by E. Spangenberg, M.E., former Superintendent St. Louis School of Engineering; Albert Uhl, A.I.E.E., former Instructor Practical Electrical Engineering St. Louis School of Engineering, and E. W. Pratt, Master Mechanic. Unquestionably the most complete work ever published and an absolute authority on all subjects relating to Steam and Electrical Engineering. Only work containing 1,055 Questions and Answers on every branch of engineering. Written by practical men for practical men in an easy, simple style so anyone can understand it. 672 pages; 648 illustrations; over 200 pages on electricity. Treats on Gas and Gasoline Engines, Stationary and Locomotive Engineering, Compressed Air, Refrigeration and Hydraulic Elevators. Students and experienced engineers and mechanics should have this book. Write at once for FREE 24-page Pamphlet that tells all about it.

**El Khazneh el Farioun (the treasury of Pharaoh) Petra.**

This is in some respects the most remarkable of the beautiful temples and tombs of Petra, the rock hewn capital of Edom and later of the Nabataeans, whose king Aretas, mentioned in 2 Cor. 11, 32, extended his conquests as far as Damascus. This monument of antiquity is thought to be the work of the Romans, being attributed by some to the Emperor Hadrian who visited the place in A. D. 131. The color of the sandstone rock from which this vast monolith was cut is a delicate rose pink. The imposing façade shows two rows each of six majestic columns. It terminates in a miniature temple crowned by a huge urn said to contain treasures of Pharaoh. The angle at which the photograph was taken will shows how the temple was cut from the rock.

A CITY HEWN OUT OF SOLID ROCK.—[See page 220.]

### THE "WHIP-CREATION" BATTLESHIP

THE Washington correspondent who is responsible for the distribution of naval and military news to the daily press of the country has been writing some extremely silly nonsense about the two battleships which the House Naval Committee has recommended for this year's programme, and he has put into the mouth of Secretary Meyer statements as to the objects which have inspired the request for these two powerful vessels which we are perfectly satisfied the Secretary could never have uttered. According to the dispatches the motive responsible for their unprecedented size, reported to be from 30,000 to 32,000 tons, is the desire to build a couple of ships which shall be bigger than anything else afloat, and give to this nation the prestige of possessing battleships which in respect of size and terror-producing qualities shall be supremely of the "whip-creation" order.

It is sufficient to say, once and for all, that the day of whip-creation sentiment has long ago passed—if indeed it ever existed except on the street or in the music hall ballad. Certainly it was never a motive in the upbuilding of the United States navy. Our frigates of the sailing days were built swifter and armed stronger than the ships then afloat in other navies, not for the vainglory of being able to say that they were swifter and more heavily armed, but for the very practical purpose of overtaking the enemy, bringing him to action, and crushing him by superior gun fire. The policy of that early time has been the policy of our navy in the intervening one hundred years, and it is its policy to-day. If Secretary Meyer believes it to be expedient to build a ship many thousand tons larger than anything contemplated abroad, we may rest assured that it is because he and his naval advisers believe that to maintain our traditional superiority in gun fire we must move up from the 12-inch to the 14-inch gun and increase our displacements in proportion.

The most efficient battleship is the one which embodies the maximum amount of all-round military efficiency on the minimum amount of displacement. Unless the present theories of naval designers are very much at fault, a ton of displacement in a big battleship gives more military value than it does in a ship of smaller size. Thus 20,000 tons in a "Delaware" is a more valuable asset than the same displacement in two "Oregons." Here then is another cause of the rapid growth in recent years in the tonnage of the first-class fighting ship. From the 12,500-ton "Maine" our ships of the first line have grown through the 16,000 tons of the "Connecticut," the 20,000 tons of the "North Dakota," and the 22,000 tons of the "Florida" to the 26,000 tons of the two great vessels "Arkansas" and "Wyoming," which are now upon the stocks.

The big jump of 25 per cent in displacement between the "Connecticut" and "North Dakota" was due to the coming of the dreadnought type and the adoption of an exclusive main armament of 12-inch guns. To-day we are on the eve of another great advance, and again it is due to a great increase in the weight and power of the battery, this time by the substitution of the 14-inch for the 12-inch gun. The House Committee on Naval Affairs has accepted, we are glad to see, the Secretary's programme for increasing the force of the navy by two battleships, two fleet colliers, one repair ship, and four submarines of a new type of unusual speed and steaming radius. According to the provisions, the battleships are to be of at least 26,000 tons, and each ship is to carry ten 14-inch guns, the ships being made of sufficient displacement to carry this battery. The 14-inch gun, however, with its mount, ammunition, etc., is so much heavier than the 12-inch that the new vessels, even though they carry two less guns, will have to be of at least 28,000 tons displacement, and if it should be decided to mount twelve such guns, the displacement may run up to 30,000 tons and over. Because of the greater punishing power of the 14-inch gun at long ranges, a battery of ten 14-inch would greatly outmatch one of twelve 12-inch. There is no ship afloat or contemplated, *so far as we know*, among the navies of the world, that could withstand such a vessel.

### HIGH-SPEED TELEGRAPHY.

SOME very remarkable testimony has been elicited by the Joint Committee of the Legislature which is investigating the question of extending the jurisdiction of the Public Service Commission to and over telephone and telegraph companies. It is remarkable as seeming to indicate that in spite of the large amount of thought, ingenuity, and mechanical skill which have been directed with marked success during the past few decades to the improvement of the speed and lowering of the cost of telegraphy, practically the whole of the business of the big telegraph companies is to-day sent by the hand-operated Morse key, in much the same way and at no greater speed, than when Morse first made telegraphy a practical commercial art. Thus, according to the testimony of Col. Clowry, president of the Western Union, the maximum speed of transmission is obtained in their service by two systems, the Wheatstone and the Barclay, the former having a capacity of 125 words per minute, and the latter of 40, with an average of about 50 in practical use, and these two forms of apparatus, it would seem, represent the only departure made by the Western Union Company from their almost universal practice of operating by hand by the Morse key.

Side by side with this evidence testimony was given that rapid telegraphy systems have been developed here and in Europe with capacities of from 500 to 1,000 words a minute and over, one system, established in several centers in the United States, being now in daily use, which is sending messages at a rate of 1,000 words per minute. The public will naturally ask, if such high speed be possible, why do not the telegraph companies make use of the system and so increase their capacity and make the corresponding decrease in rates. In his testimony Col. Clowry explained that the Western Union's is a one-message business, and that the company cannot hold messages until they get a sufficient number to send at a 1,000-word-a-minute rate. This is true as regards the single short message, but in the case of the longer messages approaching the manuscript letter length, the type of business which would be certain of enormous development if it were offered to the public throughout the whole twenty-four hours of the day at the low rates which would then be possible—it would be practicable to set half a dozen operators at work simultaneously in punching the sending tapes, and the message could be sent through in less than one-tenth the time that it would take by the present methods. The transmission of Peary's 8,000-word message from Indian Harbor to the New York Times was quoted as a great feat in telegraphy. It took a force of twenty operators three days to get the message through. By the rapid telegraphy system the same message, after being prepared on the tape, could have been sent over a single line in about ten minutes' time.

The high-speed methods as worked out by Hughes, Murray, Pollak-Virag, and Delany claim to send at the rates respectively of 4,500, 16,000, 36,000 and 60,000 words per hour. The significance of these methods to the public is that by their use the telegraph could be extended, cheapened and popularized until it was as available to the ordinary citizen as the far more highly developed telephone of the present day.

### NEW YORK AND PARIS SUBWAY SYSTEMS COMPARED.

NEW YORK CITY is justly proud of its subway system, but it will be a surprise to some of us to learn that the subway system of Paris actually carries a larger number of passengers during the year, the total being 282,000,000 as against 200,000,000 carried on the New York system. Outside of the mere fact that more people were carried the comparison is entirely favorable to the New York subway. The details of the following comparison have been worked out by R. H. Whitten, the Statistician of the New York Public Service Commission, and they afford upon a most timely subject a mass of valuable information, which is a credit to the compiler and cannot fail to be of great service to the Commission in its important work of regulating transportation matters in this city.

There are certain points of similarity between the two subways. Both have been built and are owned by the city, and both are leased for a term of years to an operating company. The length of the two systems in miles of single track operated was in 1908, the year for which the latest figures are available, very nearly equal. But the Paris system, which is entirely two-track, forms a network of lines covering a district having a radius of three or four miles from the business or traffic center, whereas the New York system has a single *stem* terminating in two long forks at the upper end, and extending 14 miles to its most distant point from the Brooklyn Bridge, which may be called the chief traffic center. The Paris subway has no express service, whereas the New York subway has four tracks carrying express and local service for six and a half miles through the most congested district.

The population of the district served by the subway system was 2,750,000 in New York and 2,790,000 in Paris. The area of the city proper of Paris immediately tributary to the subway is 31 square miles, the area of Manhattan and the Bronx served by the subway is 62 square miles. Hence the population of the district served by the Paris subway is more than twice as dense as that served by the New York system. There is a total of 64.6 miles of single track in the New York and of 62.2 miles in the Paris subway.

The great superiority of the New York system is due to the frequency of the trains and the higher speed of travel. In Paris during 1908 the least headway during rush hours was 2 minutes and 33 seconds and the greatest 7½ minutes. The least headway in the rush hours of the express trains in New York was 2 minutes and the greatest 4 minutes. The maximum length of the Paris train was 236 feet, of the New York train, 411 feet. The average speed in the Paris subway is 12 miles per hour, and in the New York subway, 18 miles per hour, the average speed of express trains between Brooklyn Bridge and 96th Street being about 24 miles per hour and the average speed of the local trains about 15 miles per hour. The maximum speed in the New York subway is 40 miles per hour, as against 21.7 miles per hour in Paris.

The rates of fare in Paris are first class 4.8 cents, second class 2.9 cents, and second class round trip tickets 3.8 cents, equivalent to 1.9 cents per trip. In New York there is a uniform fare of 5 cents, but while the fare in New York is 5 cents, the average length of ride per passenger is from two to two and a half times that in Paris.

In Paris the capacity of each car is determined by the government, and in 1908 the average number of passengers per car was 64. The capacity of the New York cars, both seated and standing, estimated on the Paris basis, was 103, but this frequently rises to 150, and even 170 passengers per car. In Paris the number of standing places is fixed by the government; in New York the limit is apparently fixed by the ability of a burly platform guard to boost the passengers in by a well-directed football rush. But were the government allotment of floor space, as obtaining in Paris, applied in New York, the maximum capacity of a New York subway car would be cut down from 170 to 103. The number of passenger place-miles per mile of track was 73,000,000 for New York and 36,000,000 for the Paris system, and yet, as we have seen above, the Paris subway, because of the shorter length of the trips, carried a greater number of passengers in the year.

Congestion in Paris is not nearly so great as in New York, first, because traffic is more evenly distributed throughout the day; secondly, because the currents of traffic in Paris move in both directions during the rush hours; and thirdly, because the passenger in Paris takes a shorter average ride, and vacates his place for others. The longest possible ride on the New York subway is 17½ miles, though it is not probable that many people take the trip from Atlantic Avenue, Brooklyn, to 222nd Street, New York, for the pleasure of the trip, and certainly not many for business purposes. The total cost of the New York subway and its equipment was $87,938,000, consisting of $51,290,000 actually paid by the city for the construction of the subway and $36,648,000 that the company claims to have expended for both equipment and construction, including $10,048,000 which it claims to have spent in the construction of the subway from Brooklyn Bridge below Broadway and the East River to Brooklyn. The total cost of the construction and equipment of the Paris subway is estimated at $62,258,000.

The New York subway fared much better than the Paris subway in the matter of taxes, the former paying but $900 per mile of single track as against $4,200 per mile paid by the Paris subway. The New York subway, considered as an economic undertaking, earned about 7 per cent on the capital invested, while the operating company earned abou[illegible] per cent on its reported investment. The Paris subway earned 7½ per cent on the total estimated cost of construction and equipment, and the operating company earned 8 per cent on its reported investment.

## ENGINEERING.

A recent wreck on the London & Brighton Railway, England, when an express left the rails and crashed into the railway station, has again illustrated the light construction of English cars A Pullman car was comparatively little damaged, whereas the ordinary day coaches were completely wrecked.

The new single-phase electric freight locomotive which has been built for the New Haven Railroad was recently given a test between New Rochelle and Stamford, a distance of 17 miles. The load consisted of thirty loaded freight cars, and the distance of 18 miles was covered in 27 minutes without pushing the engine to its full capacity

In a paper before the Engineers' Society of Western Pennsylvania, E. F Bulmahn described a new type of bituminous gas producer which embodies the good features both of the up-draft and the down-draft type overcoming the production of tar and completely consuming the fixed carbon. There are two fuel beds, one operated as a down-draft producer to break up the volatile matter, the other as an up-draft producer to consume the fixed carbon, the resultant gas being taken off at the center of the producer

Time was when it took nearly six years to build a battleship in private yards in the United States, but the construction of the "Connecticut" at the government yard at Brooklyn set a pace which has steadily accelerated. The "Mississippi," whose trials took place as recently as October, 1907, took 44 months to construct. The "New Hampshire" December, 1907, was built in 38 months, the "North Carolina" (cruiser), January, 1908, in 36 months, Michigan' (battleship), 1909, in 24½ months, the "Delaware' (battleship), October, 1909, in 27 months

Vast improvements are being made in the Trans-Siberian Railway which, in addition to being double-tracked, is being largely relocated with a view to the elimination of grades and the shortening of distance When the work has been completed the distance from Paris to Peking will be 6,300 miles instead of 7,500 miles over the present line *via* Harbin and Mukden, and the fourteen days now consumed on the trip will be reduced to nine and a half days The value of these improvements will be as great from the military point of view as they will from that of passenger and freight traffic

Speaking on the relative economy of the single-phase and direct-current systems for steam railroads Mr George Gibbs is of the opinion that maintenance costs of the single-phase system as at present developed will be somewhat higher than for the direct current though eventually they should be about the same On the other hand, he estimates that about 13 per cent less energy would be required at the power house for the single-phase than for the direct-current system Adding the saving in sub-station operation, he looks for a saving of from 4 to 5 per cent in the total operating cost in favor of the single-phase system

The tremendous floods of the past season on the Isthmus of Panama have helped to demonstrate, even before completion, the wisdom of building a high level rather than a sea-level canal Through the swamp near Gatun the bottom of a sea-level canal would be some 50 feet below the general ground level, and at Gamboa, where the Chagres River pours its enormous and sudden floods across the canal cut, the river bed would be 90 feet above the canal bottom. Under the torrential downpour, the discharge of alluvial silt into the canal would make necessary constant dredging, and might result in the temporary obstruction of the channel.

There is great activity just now in experimental work in the direction of speed-reducing gears for marine turbines. We noted in our issue of February 12th that the Melville-MacAlpine mechanical gear has shown a shop efficiency of 98.5 per cent. The Parsons Marine Steam Turbine Company have installed a helical reduction gear on the 1,000-ton steamship "Vespasian," with which they claim to have obtained a shop efficiency of 98 per cent. The Dr. Foettinger hydraulic reduction gear has shown an efficiency of 80 per cent. This last-named gear, however, is said to have the great advantage of being quickly reversible.

Prof. O. Paul Monckton of Calcutta sends us a preliminary description of an enormous steel tank, 330 feet square by 6 feet deep, carried on steel columns at a height of 90 feet from the ground, which has been built to act as a reservoir for the water mains of the corporation. Because of the limited bearing capacity of the local silt underlying Calcutta, the tank has been built upon a monolithic bed of concrete weighing 26,000 tons. The tank itself weighs 10,000 tons, and the water about 40,000 tons. The supporting columns are in groups of four, braced together; but as a precaution against the action of earthquakes the groups are not interbraced, the object being to [illegible] vibration and to provide a certain flexibility. The cost of the tank was $600,000.

## AERONAUTICS.

The latest German airship—"Parseval V"—left Bitterfeld at 10 15 A. M March 1st on a voyage to Berlin The capital city was reached safely the 80 miles being covered in 4 hours. This airship is the smallest non rigid passenger-carrying dirigible yet constructed Its length is but 30 meters (90 feet)

With the same make of 50 horse-power revolving-cylinder motor used by the ill fated Delagrange, and which drove his machine at the rate of 50 miles an hour, Le Blon flew 10 kilometers (6 21 miles) in 8 7 4/5 (45 82 miles per hour) and Balsan 5 kilometers (3 1 miles) in 4 1 (46 38 miles per hour) at the first foreign aviation meet of the year at Heliopolis, near Cairo, Egypt Both were awarded prizes.

The 1910 model Bleriot monoplane has a body only 6 6 meters (21 64 feet) in length The body is completely covered There are wide horizontal fins on each side at the rear, forming a tail, and the horizontal rudder is in two parts, one of which is hinged to the rear edge of each fin The tail resembles that of the Antoinette monoplane, but Bleriot still uses a rectangular-section body instead of the V-shaped form which imparts to the Antoinette machine its excellent transverse stability

The recent decision of Judge Hand against Paulhan in the Wright brothers' suit, the granting of a preliminary injunction, and the requirement of a $25,000 bond for one month in case Paulhan wished to continue his flights, has put a sudden end to the making of exhibition flights in America by this daring record breaking Frenchman The bond was reduced to $12,000, but Paulhan's manager although under contract to pay him $6,000 per week has brought the aviator to New York to await the result of an appeal The case will be reopened on the 12th instant

Gen. Brun, the French Minister of War a month ago inspected at Villacoublay the four Wright biplanes which have been built for the French army Count Lambert explained the mechanism but made no trial flight because of an extremely high wind At the same time the army Antoinette and Farman machines were inspected at Mourmelon by an artillery officer, Commandant Estienne On the 3rd ultimo Van den Born made a 35-minute flight in one of the Farman biplanes, carrying a useful load of 201 kilogrammes (443 pounds) On March 1st Lieut Cammaran of the Engineer Corps flew 38 miles in a similar machine Bleriot also has been instructing Lieut. Aquaviva with success

A man who has made a thorough investigation of the accident to the Bleriot monoplane which cost the life of Leon Delagrange, has concluded that the accident was the result of the aviator getting "rattled" for an instant when he was flying low and was about to turn It is this man's belief that Delagrange threw his control lever too far to one side— thus warping the wings too much and tipping the machine severely—and then too far to the other the result being that the machine swayed so violently that it turned over It struck the ground upside down, and all the guys etc on the under side were found intact A spacing strut between the wings (which the constructor claimed had been left out) was found in place and unbroken As far as could be ascertained, everything was in good order and the accident was not due to the failure or breakage of any part of the mechanism.

Now that Germany has produced several "men birds" many new aeroplane inventors are rapidly appearing The majority of these favor the monoplane, with which type the first $10,000 cash prize (the Lanz prize) was won by Herr Grade last fall. Dorner and Hilsman are two of the latest successful experimenters with this type of aeronef—to whom should be added Major von Parseval, who has a huge 14-meter (46 foot) span monoplane fitted with a 114-horse-power motor This machine is undergoing its preliminary tests on the shore of the lake at Plan in Mecklenburg On March 1st Herr Paul Lange attempted the first aeroplane flight to be made at Dresden He rose to a height of 40 feet, when a violent wind gust capsized the machine, which fell and was badly demolished. The aviator escaped with bad bruises

The making and flying of model aeroplanes is a scientific diversion from which much may be learned Several interesting new forms of aeroplanes have been developed from models, and many amateurs have learned the behavior in flight of the various types of machines. Hence the first national contest of the Aeronautic Society for the Chanute cup and other prizes, which was held in the 69th Regiment Armory, New York city, on the evening of March 3rd, was largely attended. Several small monoplanes having planes made of wood were flown by L. J Lesh Mr Dalkranian had a Langley-type machine with 4 large propellers, one at either corner All the models were launched from a table. The longest flight—148 feet—was made by the monoplane of Frederick Watkin, a 15-year-old boy. Other contests will be held weekly in the armory.

## SCIENCE.

Prof. Herschel C Parker of Columbia University announces his intention of attempting to ascend the Alaskan peak, Mount McKinley He states that either he will reach the summit or prove that it can be reached only by an aeroplane

The alcohol produced from sawdust and wood must not be confused with wood alcohol, for, although standard alcohol is primarily made from wood, it is produced directly by the fermentation of a pure sugar solution, into which the wood is first converted, and it is the same, both chemically and physically, as the alcohol made from grain

Knud Rasmussen, the explorer, will sail in June for Greenland on an expedition which will consume four years The ethnographic study of the Eskimos is the purpose of this expedition One year will be spent at Cape York and a year each at Hudson s and the Crown Bays After the navigation of Baffin s Bay Rasmussen expects to circumnavigate Alaska and to sail to the Aleutian Islands and return via San Francisco.

Sir Ernest H Shackleton, the Antarctic explorer, who is to lecture in this country, will arrive on the Lusitania on March 25th Before the explorer leaves Washington, where he will be the guest of Ambassador Bryce he will receive from President Taft the gold medal of the National Geographical Society While in New York he will be presented with the gold medal of the American Geographical Society of New York

Prof. E. E Barnard of Yerkes Observatory informs us that on February 27th last he obtained with a one-hour exposure a photograph of Halley's comet, showing a faint tail of two degrees, equivalent to a length of about fourteen million miles This is rather important in relation to the question as to whether the tail will reach the earth on May 18th From these photographs taken so far from perihelion, it seems that the tail will be amply long enough to reach the earth

The Royal Geographical Society of Italy, at a largely attended meeting ratified the recommendations of the committee relatively to the bestowal of medals and other distinctions for the year 1909 These include a gold medal to Robert E Peary for the discovery of the North Pole, silver medal to Captain Robert A Bartlett, who commanded the steamship "Roosevelt" on the Peary expedition gold medal to Lieutenant Sir Ernest H Shackleton, for his "nearest South Pole , silver tablet to the Duke of the Abruzzi for his expedition to the Himalayas where he made a record ascent

The moving picture is now applied to educational purposes Chemical tests are now exhibited on the screen There are films illustrating the electrolysis of water, action of nitric acid on silver and action of aqua regia on metallic gold etc The test tube is thrown on the screen many times enlarged, and the chemical action is clearly illustrated Most unsavory but educational is a film illustrating the peril of the fly The flies are shown laying eggs in unsavory places and before the eyes of the spectators the eggs develop in heaps of wriggling maggots In the final stage the winged fly is shown in all its unsanitary glory Still another film exhibits the acrobatic fly lying on its back juggling various articles with its feet and even swinging a dumb bell as large as the insect itself

In the possession of Knox Hall of Natural History with its invaluable specimens Hamilton College is especially fortunate. By the kindness of the Hon James Knox, LL D '30, the original building was reconstructed into a hall suited to the display of all sorts of natural history specimens The most important collection on exhibit is that of the New York State minerals, together with related minerals from Canada. Among these specimens are found many rare ones the best of their kind in existence In addition to these minerals are 2,400 specimens of fossils and rocks to illustrate the geology of New York, 1,750 specimens to illustrate the geology of the United States, 600 fossils, mainly from the Silurian formation of Europe Several thousand valuable specimens in paleontology 10,000 specimens of ores and minerals 2 000 specimens of land, fresh water, and marine shells 300 specimens in ornithology from China, 13 000 specimens in entomology, supplemented by a fine group of specimens in ornithology and comparative anatomy A rare collection of Japanese shells and insects A large and useful exhibition of the North American flora, the result of fifty years of botanical study, search, and correspondence A large and valuable collection of butterflies, appropriately mounted The Hall of Natural History is under the charge of Prof William John Miller, Ph D., an eminent authority on geology and mineralogy Dr Miller recently wrote a treatise on "The Geology of the Remsen Quadrangle" including Trenton Falls and the vicinity in Oneida and Herkimer counties. This book was published by the University of the State of New York as Bulletin No. 126 of the Education Department.

# DRIVING PILES WITHOUT A PILE DRIVER

BY GEORGE H. LODGE

It may be of interest to many of the readers of the SCIENTIFIC AMERICAN to learn of an easy method of driving piles through the ice without the use of a pile driver

Those who have tried to drive even a small post by hand while working in water or from a small boat have found it much more difficult than one would at first suppose I was myself confronted with the problem of building a dock landing for a lake steamboat—a steamboat built to carry 300 passengers, being 70 feet long The problem was to build a dock or landing safe and large enough to handle the people rapidly

First we thought that it would be necessary to hire a pile-driving outfit, but my father, R H Lodge, devised a plan that works to perfection

We select straight white oak piles not over one foot in diameter at the butt which are cut to the length required usually from 20 to 36 feet These are sharpened at the butt ends to a point and with an ax a thread is cut from the point of the stick back from three to four and one-half feet, according to the size of the pile

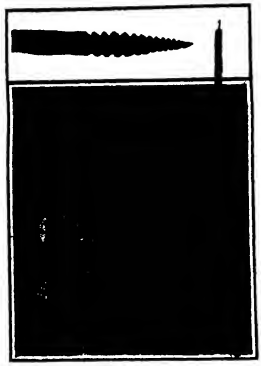
It is important that the threads be cut as nearly the same distance apart as possible A good man with an ax can soon cut threads that are mechanical. It is astonishing how many, with a little practice, can be cut in a day It pays to use special care in the cutting, as it helps wonderfully in the driving. Piles that are from ten to twelve inches in diameter should have threads from three to three and one-half inches apart and two to two and one-half inches deep

After the threads are cut the pole is ready to drive, which is done by chopping a hole through the ice at the desired spot, being careful not to make the hole over two inches larger in diameter than the pole, and have the ice act as a guide to keep the pole upright while screwing it down

If the pole is long and heavy, it is necessary to fasten three guy ropes to the top of it before raising After the pole is raised, it is an easy matter to keep it plumb by pulling the ropes

The pile is raised like a common telephone pole in other words, a little at a time with pike poles, following up under with two planks spiked together in the form of an X.

It is a good plan to stand a plank in the hole and to let the point of the pile rest against it, as it assists in placing the pile in the desired spot



DRIVING PILES WITHOUT A PILE DRIVER.

It is also a great help to spike a short plank across the pile, temporarily, just above the threads, to keep the pile from shooting under the ice before it is vertical whereupon it may be knocked off The pile will then drop into the proper place

Now you are ready to bind a pole (or sweep lever) to the pile. This is done with a common log chain, care being taken to bind it so that it can be screwed in the right direction. Hitch a sharp-shod horse to the outer end and lead him around the pile (capstan fashion)

It is an easy matter now to screw a large pile from four to eight feet into solid clay or gravel or to unscrew it and remove it

The accompanying photographs illustrate the wooden threads ready for use, and the plan of screwing in a left hand threaded pile by the aid of a horse. We often put in smaller poles by hand, using two or three men instead of a horse.

We have recently taken out two steamer tie posts that have been in use for eight years, having begun to decay These unscrewed posts we found had been in sixteen feet of clay and quicksand It was necessary to hitch the lever below the water line, where the wood was sound, in order to start them.

---

To the Cairo Scientific Journal for January last Mr B F E. Keeling communicates an interesting paper on climate changes in Egypt. There is a strong belief among residents that changes have occurred within the last ten or twenty years (possibly due to increased irrigation) which are distinctly "sensible" without the aid of instruments. Mr Keeling quotes the mean temperature at Abbassia for each pentade from 1870 to 1904, and for the four years 1905-8, but the results show that the differences are hardly greater than might be caused by difference of exposure of the thermometers. As regards humidity, also, there is very little evidence of any decided change during the last forty years It is confidently asserted by many persons that the rainfall has increased during quite recent years, but the author shows that there is little, if any, evidence of such being the case The total rainfall of any year is often influenced by the fall on a single day, and is consequently very variable from one year to another, the driest year on record at Abbassia is 1892, with little more than a quarter of an inch of rain, and the wettest, 1904, with less than 3 inches, the mean for 1887-1908 being approximately 1.4 inch.

# AN ARTISTIC REINFORCED CONCRETE BRIDGE

## A COMING TYPE FOR COUNTY HIGHWAY BRIDGES

In country districts where the materials are readily accessible the reinforced concrete bridge should prove to be an ideal system for the construction of concrete bridges of moderate span We say of moderate span, for the reason that the art of trussed bridge construction in reinforced concrete is as yet in too early a stage of its development to warrant its indiscriminate use in bridges of considerable span In structures of moderate length, say up to about eighty or a hundred feet, if care is taken to proportioning the parts, especially at the joints, and very particular care is taken in securing a thorough bond between concrete and steel, the county commissioners or other authorities should find the concrete steel bridge a reliable and economical type. It is easy to erect, it requires no painting and practically no maintenance whatever, it is indestructible by fire or the action of the weather, and its subsequent cost for maintenance should be practically nothing at all

The accompanying illustration shows a bridge of this class of the bowstring type which was recently built in Canada It has a span of 80 feet and provides a clear roadway 16 feet wide. The total weight is about 160 tons, and it contains about 13 tons of reinforcement in the form of plates and round rods.

The bridge was designed to carry a load of one hundred pounds per square foot evenly distributed, and it was tested for this load with an additional load of 35 tons represented by a herd of 70 cattle

On the score of appearance it must be conceded that the design is decidedly pleasing the intersection of the balustrade with the chord and web members having been worked out with considerable taste The structure spans the Etobicoke River, in the counties of York and Peel, Canada

---

No sooner had the first modest attempts to steer ships by aerial electric waves been crowned with more or less success, than endeavors were made to direct the course of balloons and aeroplanes in the same manner The American engineer Anthony has made experiments off Sandy Hook, with a small unmanned dirigible balloon, which he succeeded in guiding more than a mile seaward and bringing back to the point of departure Prof Wiechert suggests the employment of unmanned aeroplanes for the study of atmospheric electricity and has designed an apparatus of this kind It is obvious that such an apparatus, equipped with the necessary instruments, which could be sent to great heights without danger and brought back with certainty, would be much more useful for the study of the atmosphere, and especially that of atmospheric electricity, than unmanned registering balloons, the recovery of which is always a matter of chance, or manned balloons and kites, the use of which is not unattended with danger in stormy weather Balloons controlled from a distance by electric waves would also be very useful in the rescue of shipwrecked persons and for many military and other purposes. But—and this objection applies also to the wireless direction of ships and torpedoes—it is a long step from successful experiments in favorable conditions to uniform success in practical use.—Prometheus.

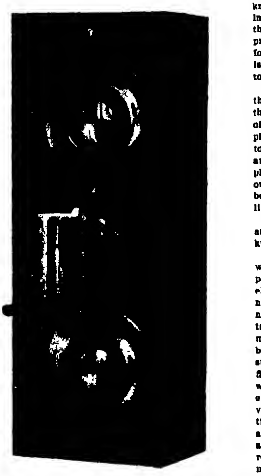
A REINFORCED CONCRETE BRIDGE OF ARTISTIC DESIGN.

# Instrument for Detecting Violations of the Speed Laws

BY L. GORDON GLAZIER

A very ingenious instrument for recording the speed and license number of an automobile has been devised by two instructors of the Massachusetts Institute of Technology. The instrument, which is but little larger than a pocket kodak, consists of a double camera with a watch movement which controls the operation of the camera shutter.

When an automobile passes at a speed that seems excessive, the operator trains the instruments upon it and releases the mechanism by pressing a button. Immediately the shutter of the upper camera is sprung



DOUBLE CAMERA WITH WHICH VIOLATIONS OF THE SPEED LAWS ARE DETECTED.

taking a photograph of the receding automobile, and a moment later the other shutter is sprung, taking a second image of the automobile, whereupon the timing mechanism comes to a stop. The plate is developed by the regular process, and the resulting negative shows an image of the automobile near the operator with its license number distinct, and a second view of the machine taken at the end of the time interval. In the center of the print are the photographs of the hands of the stop watch caught when the first and second exposures were made.

Since the automobile has traversed a certain space in the time interval, the second image is smaller than the first by an amount which can easily be measured with an ordinary scale, divided in hundredths of an inch; and knowing that the standard wheel tread is 56 inches, the distances of the two objects from the camera and hence the space the automobile has covered in the time interval is easily found by the following law. The distance of any object from the lens is as many times greater than the focal distance of the camera as the length of any line of the real object is greater than its length in the photograph. This is a simple proportion in which three of the terms are known, namely, the size of the object, the size of the image of the object on the plate, and the distance of the image from the lens. The fourth term of the proportion, the distance of the object from the lens, follows by simple division. However, the operator is saved all irksome computation by a table attached to the instrument.

To overcome the possible objection by the courts, the watch has been designed so that the operator of the instrument may actually see it during the process of taking the picture. This is made possible by simply boring a hole from the outside of the camera box to the back of the watch, which brings to view a dial around which travels a hand attached to the same pinion or staff as the regular hand of the watch. In order to see this dial more plainly, two mirrors have been placed permanently in such a manner as to illuminate it.

The instrument gives extremely accurate results, and can be calibrated from time to time on objects of known speeds.

The inventors believe that the instrument should be welcomed by autoists as well as police. It is an impartial judge, the personal element being entirely eliminated. A motorist who has been stopped does not have to rely on an officer's estimate of the speed, nor on the speed claimed by the officers operating a trap by means of stop watch and signals. Dozens of motorists are fighting cases every day who honestly believe that they were not overspeeding when stopped. They would be perfectly willing to pay their fines if convinced they were violating the law. Even where the more rational view is taken that the speed alone shall not determine whether or not a man is violating the law, but that the speed taken in connection with the surroundings shall determine it, it is always a question of the officer's word against the autoist's as to surroundings. This photographic speed recorder shows whether there were several vehicles near the automobile, whether people were crossing the street, whether it was more than ordinarily dangerous to run at the speed indicated, or more than ordinarily safe.

A great advantage of the instrument is that it records speed over a short distance. In the congested portions of cities, near crowded cross streets and in similar situations, it offers the only existing method of measuring momentary bursts of speed. The record of any reckless driver can be easily obtained and a print sent directly to him, when he cannot deny the evidence of his own eyes, and in many cases an arrest will not be necessary, as the offense will not be repeated.

Regarding the legality of this speed recorder in a recent case that was strongly contested Judge Hammond of the Massachusetts Supreme Court said "The result of the evidence did not depend upon the fluctuations of human agencies nor on conditions where relations to results were uncertain, but upon the immutable working of natural laws, and upon the

SPEED OF AN AUTOMOBILE SHOWN BY TWO CONSECUTIVE PHOTOGRAPHS

evidence the presiding judge may well have found that such experiments were likely to be more reliable as to the speed of the automobile than the conjectural statement of an eye witness or the interested statement of a chauffeur."

### Sacrificial Compliments Paid to New Buildings in Antiquity.

A superstition that still envelops a great part of the earth is that especial firmness may be given to a building and that it may be protected from hostile influences by inclosing a living creature, preferably a human being, in one of the walls of the building itself. This belief, which is particularly prevalent in the Balkan peninsula and, for instance, has given to the Roumanian Queen, Carmen Sylva, material for one of her most beautiful folk tales, has not been known as having had any hold in Italy hitherto. Recently, in the course of archæological research, it was found that in the foundation of the Temple of Fortune in Pompeii there was a hollow space in which nothing other than the shell of a tortoise was found which time had broken into four pieces. Here, consequently, was proof of the precise immurement of a tortoise, which was enhanced by the disposition of the square blocks of stone of the creature's prison. In Italy this superstition may have passed at an early day into oblivion, as the sacrifice of human beings was foreign to the Roman religion, and was practised occasionally only under Greek influence. As, however, the sacrifice of human beings among the old Greeks was not unusual, and in Greece, as well as in the adjacent countries the tradition of sacrifice to new buildings is still insistent, it may be believed that in old Greece also the sacrificial compliment to new buildings was not unknown. Instances of this kind of sacrifice in antiquity are certainly not frequent, all those of which we have any knowledge are attributed to the Greek Orient. Usually a maiden was sacrificed who, at the same time, became the guardian spirit of the structure. For this reason Trajan effected the erection in the theater at Antioch of the statue of the girl who has been sacrificed on the occasion of the reconstruction of the city after an earthquake and was designated as Tyche, the Goddess of Fortune of the scene of her sacrifice. It is this idea which still lies to-day at the root of this superstition of sacrificial compliment. Solidly a human being is incased in a wall of a house or other building, so that its soul may live in the structure and never escape from it. At the present day a vicarious sacrifice takes the place of such immolation. The human sacrifice is practised symbolically only, either by taking the measure of a person, or of the shadow, and immuring the string representing the measure or by incasing in the wall an animal already killed or still alive. Manifestly such a vicarious sacrifice is the tortoise of the Pompeiian temple, and probably the tortoise was selected because this animal can live a long time without nourishment, and the builders believed that the charm was more effective the longer the entombed creature lived.

### The Hangman's Rope.

When death is caused by hanging what proportion does the pull to which the rope is subjected during the struggles of the victim bear to the weight of the body? This novel question has been asked and answered by experiment by Dr. Angelo de Dominicis. The tension in each case was measured by a dynamometer attached to the rope. A living dog, suspended in such a manner that it remained quiet exerted a pull of 20 pounds, but the subsequent "hanging" of the same animal produced a pull of 42 pounds. With a larger animal the corresponding tensions were 50 pounds and 103 pounds.

Hence it appears that the convulsive movements of the victim may increase the tension of the rope to more than twice the weight of the body. This result explains the occurrence in the bodies of persons killed by hanging of serious lesions which it would be difficult or impossible to produce by hanging up a corpse. The strength of the rope must also be taken into account. If a body is found suspended by a rope the breaking strength of which is little greater than the weight of the corpse, it may fairly be inferred that the body was not suspended until after death. Hence the experiments furnish valuable data for determining the cause of death in such cases and will probably be made use of in some future detective story.

# JUPITER AND HIS SATELLITES

BY PROF. FREDERIC R. HONEY, TRINITY COLLEGE

Jupiter and his satellites command especial attention at the present time, owing to the fact that this greatest of all the planets and second only to Venus in brilliancy, is approaching opposition which will be reached on March 30th Jupiter will then be both morning and evening star

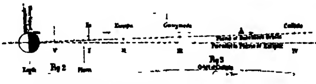
The comparatively recent increase in the number of Jupiter's satellites from four to seven and possibly eight as revealed by the growing power of the telescope directs the astronomer's curious scrutiny upon the Jovian system The satellite which is nearest the planet revolves around its great primary in the short space of twelve hours, at a distance of only 68,400 miles from the surface, while the outermost moon shows its extreme remoteness from its center of attraction (the enormous distance of 7 430 000 miles) by a revolution requiring 265 days Thus is exemplified a perfect conformity to Kepler's laws A small magnifying power reveals the elliptic outline of Jupiter, whose polar depression is extremely marked the equatorial and polar diameters showing a difference of over 5000 miles

In the plot of the orbit Jupiter's position is shown for the date of opposition, which is very near aphelion, also for the oppositions from 1902 to 1911 inclusive The average interval between oppositions is 399 days. But, in obedience to Kepler's second law, the planet's velocity at aphelion is diminishing. The last opposition occurred on February 28th, 1909, and the next will occur on April 30th, 1911 At perihelion the velocity was accelerated The dates of the oppositions, which occurred before and after the perihelion passage were respectively September 11th, 1903, and October 18th, 1904

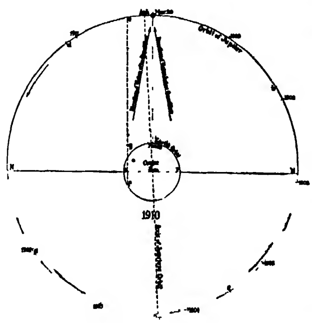
The five inner satellites revolve in orbits whose planes very nearly coincide with that of Jupiter's equator This plane forms a small angle with the ecliptic, and may be represented approximately by a straight line (Fig 1) The distances from Jupiter to the satellites are represented by the same scale as the planet It is impossible to show the positions of the two outer satellites by this scale within the limits of this page, since their distances from Jupiter are over six times that between the planet and Callisto. It should be noted that all the satellites are never on the same side of the planet at the same time, as shown in the figure This view of the satellites' orbits is obtained when Jupiter reaches the positions $A$ and $B$ shown in the plot of the orbit. When Jupiter is near either of these points, the five satellites appear to move back and forth in straight lines, and at every revolution of each satellite there is alternately a transit across Jupiter's disk and an occultation by the planet Fig 1 shows Jupiter and the orbits as seen from the earth in 1908 In 1902 this figure was reversed During Jupiter's revolution around the sun in 11 86 years, the planet and the satellites are continually changing their positions relative to the ecliptic The plane of the orbit is inclined at an angle of 1 3 deg, and that part which is above the ecliptic is represented by the full line The line joining the points $N$ and $N'$ (the ascending and descending nodes) is the intersection of the plane of the planet's orbit with that of the ecliptic In Plot 1 a visual ray $A$ from the earth tangent to the planet shows that, seen in this direction, Callisto is no longer occulted by Jupiter Between the positions $A$ and $C$, and between $B$ and $D$, the orbits very gradually open out to the elliptic form, and at $C$ and $D$ the length of the minor axis reaches its maximum

Fig 3 represents the orbit of Callisto when the satellite no longer suffers occultation by Jupiter Cessation of occultations evidently begins some time before the date when the eclipse opens to its maximum width. But the diameters of the orbits of the four inner satellites are smaller, and with them transits and occultations continue There will be no occultation or transit of Callisto or its shadow this year after January 25th On this day the shadow was projected on Jupiter between 9 h 11 m and 10 h. 5 m. In the plots of the orbits of Jupiter and of the satellites the general directions of the lines of vision from the earth before and after opposition are indicated by arrows.

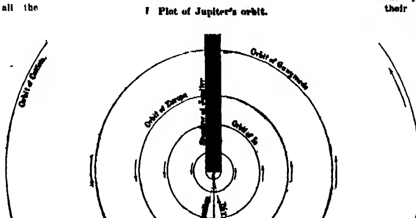
Obviously the planet does not occupy the same position in its orbit as that shown in the plot before and after opposition But if this page be rotated clockwise and counter clockwise through small angles, one position will represent Jupiter in his orbit before, and the other that after opposition Before opposition it is clear that the transit of the satellite's shadow precedes that of the satellite, and after opposition the satellite precedes the shadow For example Ganymede's shadow crossed Jupiter's disk on January 7th between the hours of 14 h 44 m, and 17 h. 31 m. (W M T) The shadow was clear of the planet before the transit of the satellite commenced two hours and twenty minutes later On June 28th the same satellite will cross Jupiter's disk between the hours 8 h 56 m and 11 h. 37 m.; and the shadow will follow 2 hours and 37 minutes later When a satellite passes into the shadow of its primary, it is described as "eclipsed." The dates of the transits of the satellites and their shadows, and of the eclipses and occultations, are given in the Nautical Almanac for ten months. For one month before and after conjunction (October 18th) when Jupiter's proximity to the sun will be too close for observation, the phenomena of the satellites are omitted.



Relative positions of Callisto, Jupiter and the Earth.



I Plot of Jupiter's orbit.



II. Plot of Jupiter's orbit and of his satellites' orbits.

JUPITER AND HIS SATELLITES.

Observations of the occultations of Jupiter's satellites provide a valuable means for verifying the velocity of light. As the earth recedes from Jupiter after opposition, an occultation is observed to occur after a longer interval of time than that which would elapse if the planets were separated by a constant distance, and after conjunction, when the earth is approaching Jupiter, the intervals are observed to diminish Light crosses the earth's orbit in a little less than a thousand seconds $\frac{185{,}800{,}000}{186{,}330}$ = 16 m. 37 s. At the date of opposition this year Jupiter's distance from the earth is 413.8 million miles. Occultation of a satellite at this distance is observed on the earth $\frac{413{,}800{,}000}{186{,}330}$ seconds, or 37 minutes after its occurrence. The points $e$ and $f$ are respectively the positions of Jupiter and the earth at the same date when the projection on the plane of the ecliptic of the line connecting the planets is parallel to that of March 30th At the second date, when the earth is at $f$, observation of a phenomenon of Jupiter's satellites occurs later than would be the case if the earth remained at the constant distance ($ge$) from Jupiter, and the difference in time is that represented by the interval $gf$, or $\frac{gf}{AP} \times 997$ seconds.

A comparison of the earth and moon with Jupiter's satellite system is shown in Figs. 1 and 2, which are drawn to the same scale. The moon's distance from the earth does not differ very much from Io's distance from Jupiter The revolution of the latter is accomplished in 1 77 days, and of the former in 27 32 days. If Io's distance were reduced to correspond with that of the moon from the earth, the period of the satellite would be even shorter than that which is given in the table The rapid revolutions of the planet's satellites maintains them in their orbits in opposition to the great central force attracting them to Jupiter, whose mass is 318 times that of the earth In the table the diameters of satellites V, VI, and VII are not given They are too small for accurate measurement, the diameters ranging from 50 to 100 miles.

That the controlling devices for a single-phase car equipment need not be more complicated than for a direct-current car, states the Electrical World, will be apparent at once from the fact that any of the methods now used with the latter type of car can be applied immediately to the former without alteration. It is evident that by selecting a suitably low value of trolley E. M. F the familiar series-parallel arrangement of motors with rheostatic acceleration can be applied to series motors of the single-phase type equally as satisfactorily as to those of the direct-current type. Moreover, with the alternating-current equipment it is possible to substitute reactance coils for the resistance of the rheostats, and thereby eliminate a considerable portion of the energy dissipated as heat in the control circuits during acceleration In addition, with the single-phase car there can be obtained, conveniently, any desired number of voltages to be impressed upon the motor circuits, and there is thus no necessity for limiting the E. M F. to a single value, as must be done with direct-current equipments. To this latter fact is attributable the essential difference between the controlling circuits of single-phase and direct-current cars.

## A REMARKABLE PHENOMENON.

To the Editor of the Scientific American

I have just read with interest on page 138 of the Scientific American of the "remarkable phenomenon" observed by Mr. V. J. Laine, in which a rainbow was seen to be disturbed after each peal of thunder Mr Laine's explanation, based upon the change of size of the rain-drops, is apparently unwarranted, inasmuch as according to the old and generally accepted optical theory of the rainbow, the angular position of the colors of the bow relative to the direction of the sun and the observer's eye, is independent of the size of the rain-drops.

To the writer the phenomenon is more plausibly explained by recognizing the atmospheric disturbance in the line of sight of the observer due to the thunderbolt. The light, after dispersion by and reflection from the rain-drops, passes through air which is agitated by the concussions following the lightning strokes, and the intense sound waves radiating therefrom The result is similar to that seen over a hot surface, as a stove or heated field, where the convection currents distort the light rays traversing the overlying air.

While it is true that ordinary sound waves do not affect the density of the air sufficiently to deviate the course of light perceptibly, the violent expansion and contraction accompanying a thunderbolt may produce the result. The peculiar circumstance in the case referred to is that the storm approached from the east, opposite to the sun, so that the lightning discharges, which are generally in the advance portion of the storm cloud, occurred in the vicinity of the observer and between his eye and the apparent position of the rainbow, whereas ordinarily when a rainbow is seen in the east it is after the storm has passed over and the lightning is taking place in the distance beyond.

Washington, D. C.

## THAT CURIOUS WATER PHENOMENON.

To the Editor of the Scientific American

I observed a similar curious phenomenon to that reported by James S. Lee in your issue of January 29th Mine was observed from a train going west through the great Alkali Desert in Nevada. The desert floor is of sand, and flat, as though laid by water Innumerable desert or beach grass mounds covered perhaps ten per cent of all the surface. These mounds or dunes vary from six to twenty feet in diameter by one to two feet high

It was about five o'clock of a warm September afternoon I noticed, looking westward and nearby, what seemed to be a small but powerful stream of water or fountain, going to perhaps twenty-five feet in height. Close observation revealed many hundreds of these fountains. As near as I could make out, there was one from the center of each of the sand dunes, varying in size much as the sand dunes varied in area. These fountains were really formed by incipient cyclones carrying sand, not water, in small streams, somewhat in the shape of slender long-waisted hour-glasses, spreading at the top to fall to earth. These varied from twenty to fifty feet high. The train was making the usual rather slow desert time, which gave a fair chance for observation. This continued for ten miles along the line What caused them? I suppose the floor of the desert was several degrees cooler than the sand dunes, which had been absorbing solar heat rapidly all day As evening approached, the warmer air over the dunes rose rapidly, assuming the natural spiral motion, licked up warm dry sand, and made a most beautiful picture. The passengers gazed and wondered 'why.'

Will the Editor please give the correct cause if mine, as given, is incorrect?

Roy T Kimball.

San Francisco, Cal.

## WANTED: AN ELECTRICAL APPARATUS FOR LOCATING SUNKEN TREASURE.

To the Editor of the Scientific American

I have been unsuccessful in finding in England any manufacturer of an improvement upon the under-water electrical ore-finding apparatus originally described in the Supplement of your paper dated January 20th, 1906.

I am attempting to locate the position of the hull of a wooden ship about 120 feet long by 40 feet beam, which has on board forty-four cannon and a considerable quantity of cannon ball, aggregating approximately about 20 tons in weight. The ship is also believed to contain a number of silver and copper coins. The hull is covered by about 20 feet of sand and mud, and she lies in about 70 feet of water in an extremely sheltered bay. Her position is known to within 100 yards. As the vessel belonged to the Spanish Armada, she possesses considerable historical interest. I desire to get into communication with some one who would be able to construct any improvements upon the instrument described in your Supplement of the above-mentioned date, and who would give a preliminary test of the apparatus, to show that it could fulfill the working conditions necessary I would also like to know the cost of the instrument.

Kenneth Mackenzie Foss, Lieutenant Colonel

London, S. W

## The Wisps of Saturn.

In a recent bulletin, Prof Percival Lowell of Flagstaff, Ariz., announces that on September 19th, 1909, in examining Saturn he noticed what seemed to be faint lacings traversing diagonally the planet's equatorial belt Not only was the phenomenon unprecedented, but it was so faint and illusive that he was unable at first to assure himself of its objective reality On mentioning his impressions to his assistant, Mr E. C Slipher, he found to his surprise that he had had suspicion of the same thing on September 9th, and had even thought to detect traces of it on the photographs of Saturn taken by him afterward on that day At the same time that Lowell divined rather than described the wisps he saw unmistakably a fine dark irregular line running longitudinally through the middle of the bright equatorial belt, a line not of uniform character, but as if composed of beads strung upon a wire.

Following up the eye-hint thus vouchsafed he examined the equatorial belt for the wisps at moments of good definition during the succeeding days. Repeated observation of them, both by him and his assistant, eventually showed them to be facts, and then, to clinch the matter, he succeeded in getting, on November 4th, some excellent photographs of the planet in which they stood recorded, appearing *in situ* in successive images on the same plate

The manner in which the photographs are taken enables one to eliminate on the images imperfections due the apparatus from features due the planet itself, for not only is the plate moved first horizontally and then vertically for the successive images, but the color-screen through which the photographing is done is itself shifted at intervals during the taking of the plate Nothing due to either cause could, therefore, perpetuate itself *in situ* on images of the set some distance apart

On the photographic plate the images appear exactly as they do to the eye, though of course not so well defined, to wit as wisps or filaments, fainter than the dark belts of the planet's disk, crossing the bright equatorial belt. Like all astronomic phenomena previously unperceived, they became much easier to catch after their presence was known, their recognition not being nearly so difficult as their discovery Their apparent lack of contrast with their surroundings is for much in this, which is also why the photographs which intensify contrast brought them out.

In look the lacings resemble faint shreds of some dusky substance in the act of dropping from points on one edge of the bright belt over to the other Though darker than the bright belt, they are much lighter than the dark belts from which they come a difference in tone which is probably due to their real slenderness being spread out by the light waves and so thinned in strength.

Careful scrutiny revealed that the wisps started from triangular spots in the dark belt, and Mr G R Agassiz, who was observing with Prof. Lowell, detected that the adjacent parts of this belt were themselves crisscrossed by darker lines. The triangular spots are not difficult, giving the edge of the belt in good seeing a notched or toothed appearance It has not been possible as yet to use the wisps for timing the rotation periods of Saturn's equatorial region, owing chiefly to their number and the confusion consequent upon it, but identification will undoubtedly come in time and give us a more accurate value of the equatorial speed than we at present possess.

Interesting as the lacings are in themselves, they become doubly so from this fact, that they almost precisely parallel the phenomena recently discovered on Jupiter, in the same regions. Except for faintness, which Saturn's greater distance both from the sun and from us alone would cause, the one set of features is almost a replica of the other. Like the Jovian, the wisps seem to be more tenuous in the middle of their course. Like the Jovian equatorial phenomena, too, the medial core is more conspicuous than the wisps.

The Saturnian lacings cross the equatorial belt usually at an angle, but one which is less than that of the average of the Jovian ones. This angle should have something to say about the factors concerned in the formation of the two sets respectively; for analogy is best explained by secondary difference.

## The Current Supplement.

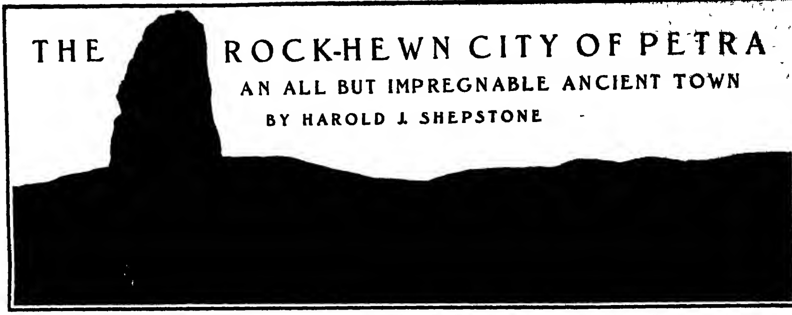
A new process for reducing atmospheric nitrogen, invented by Dr Schonherr is described in the opening article of the current Supplement No 1784 Among the present wonders of science none stirs the imagination so powerfully as the doctrine that some forms of insanity are the result of a chemical change in the blood The theory is elaborately discussed in an article entitled, 'The Chemistry of Insanity" The recent development of aeronautics has suddenly created a demand for large quantities of hydrogen at a low price The subject is considered in a short article Emil Kosack writes an article on speaking magnets, speaking iron, and speaking wire Since the experimental bombardment of the "Belle Isle" of the British navy, no such thorough and systematic firing tests have been directed against a warship in any foreign navy as those of which the French warship "Jena' was the subject last year An elaborate article by a competent authority gives the results of the tests. W P Dreaper exhaustively reviews the artificial silk industry One of the most recent important events in the field of prehistoric archæology was the discovery of a megalithic monument of remarkable size in Bisceglie Italy This subject is discussed in an illustrated article In the middle ages falconry, or hawking, was regarded as the king of sports, as it was the sport of kings The origin and development of this obsolete form of hunting is discussed by Dr Hans Bolluner in an article entitled 'Falconry in the Middle Ages" Perhaps the most distinguished authority on the subject of precious stones in Germany is Prof M Bauer of Marburg He contributes an exhaustive article on artificial stones which contains a wealth of technical information The process of directly producing ammonia from coke-oven gas is described Since Davy, nearly a century ago, constructed the first safety lamp, inventors almost innumerable have produced lamps bearing their names but in the majority of instances the alleged improvements have been more apparent than real A comparative estimate of the safety of these various forms of miners' lamps is presented by J B Marsaut F W Henkel contributes an article on astronomy and astrology, in which he riddles the supposed influence of the planets upon human affairs

After three successful flights on March 2nd, Lieut. B. D. Foulois in a Wright aeroplane, made a fourth attempt at San Antonio which resulted disastrously The rudder of the machine was wrecked and Lieut Foulois had a narrow escape from injury The machine had just turned the southern end of the parade field at Fort Sam Houston when the engine stopped The aeroplane fell forty feet to the ground

# THE ROCK-HEWN CITY OF PETRA

## AN ALL BUT IMPREGNABLE ANCIENT TOWN

### BY HAROLD J. SHEPSTONE



**The rock-hewn obelisks of Petra.**

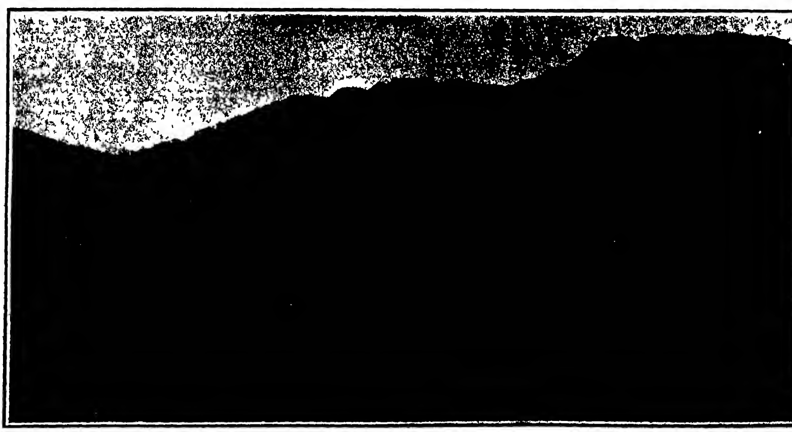
The view is taken high up to the south of the narrow valley called the Wady Mouse (the Vale of Moses) in which the famous rock-cut city of Petra reposed in ancient times, securely shut in from attack of the marauding desert tribes. It is on what bears the name of the Mountain of Obelisks, so called from the huge monolith pillars that have been made with incredible toil by cutting away from all around them the mountain top. Their height can be judged by comparison with the figure of a Bedouin standing by one of them. They are evidently Egyptian in their conception and design, as also are many of the pylons and temples of Petra.

Unique among the many wonders of the Orient and the remains of hoary civilizations stands Petra the rock hewn city the city so graphically addressed by the prophet as Thou that dwellest in the clefts of the rock, whose habitation is high (Obad 3), and referred to in the challenge of the Psalmist (60 9) "Who will bring me into the strong city? Who will lead me into Edom?" It lies on the northwest edge of the great Arabian desert about midway between the Gulf of Akabah and the Dead Sea. Other ruins such as Palmyra and Baalbec, show crumbling piles of magnificent architectural monuments but in Petra, high up among the mountain crags that sentinel it, are temples theaters, tombs, and other structures, strong and indestructible, standing almost as perfect as when they were chiseled out of the living rock of which they still form a part.

These ruins (if ruins they may be called) challenge admiration by the variety of styles they embody, showing, in the most ancient creations early native art intermixed with Egyptian and in the later magnificent edifices the best types of Greek and Roman architecture, and by the exquisite hues of the sandstone from which they were hewn, varying from the prevailing purplish red of the mountains and cliffs to the delicate pink and rose color of some strata, and the white crimson yellow and blue-ribboned veins in other places, rivaling the softness of the plumage of birds or the petals of flowers.

Petra, so long inaccessible because of its remoteness and the danger from roving Bedouins, may now be reached by a six hours' ride westward toward the Arabah from El Maan, a station on the new Mecca railroad. Prof Gustaf Dalman, director of the German Archeological School of Jerusalem and the author of a monumental work on Petra, has just paid another visit to this scene of his former explorations, in which he was accompanied by photographers of the American colony in Jerusalem, who secured a number of photographs of these majestic ruins, some of the most striking of which we here reproduce for our readers.

Petra nestling amid its precipices and cliffs almost in the shadow of Mount Hor, called by the natives Jebel Harun (Aaron) from the tradition that it was here on the top of the mount that Aaron died, is approachable only from the east through a deep and narrow defile which the little stream of the Wady Musa has in past ages cut for itself in the red sand stone. The gorge opens in one place to about two miles in width for a distance of about a mile, and here, protected by mountains and precipices on every side, this remarkable town lay secure from attack from without. It was its impregnable position and its being on the great caravan route to the Red Sea from the north that gave it the importance it had as a trade depot and stopping place. The approach was beneath a grand arched portal at the mouth of the Sik (as the deep ravine is called), some remains of the portal being still visible. It takes half an hour to follow the windings of the narrow path along the dark ravine, which is only from 10 to 20 feet wide, threading the course of the oleander fringed stream bed until one emerges into the small open valley. The variegated sandstone rocks rise precipitately on either side to the height of from 100 to 165 feet, almost shutting out the light of day. One of our views shows the entrance to the Sik. Another is taken about twenty minutes in from the opening, giving a good idea of the narrowness of the defile and the precipitousness of the rock walls, while beyond, where the gorge widens a little, are seen the sculptured columns of the magnificent so-called Khaznet el Farioun (the Treasury of Pharaoh) although it is one of the latest of the rock hewn monuments of Petra being attributed to the Emperor Hadrian who visited the place in A D 131 and erected here a temple to Isis. Another of our photographs shows this imposing structure, which is justly regarded as one of the wonders of the East. The rock wall from which it is hewn is here an exquisite rose pink. It is in a state of remarkable preservation. The imposing façade shows two rows each of six majestic columns one row above the other, with niches in which are rock-



This is a general view of Petra a city of antiquity carved out of the living rock. The entrance to the Rock City is the most striking gateway to any city on our planet. It is a narrow rift or defile, bisecting a mountain of many-hued sandstone, winding through the rock as though it were the most plastic of clay. This Sik, or defile, is nearly two miles long. Carved with matchless skill, after the conception of some master mind; gathering the beauties of the stream, the peerless hues of the sandstone, the towering cliffs, the impassable ravine, the brilliant atmosphere, and the fragment of blue sky above, the city stands unique.

**PETRA: AN ANCIENT CITY CARVED OUT OF A MOUNTAIN OF SANDSTONE AND ENTERED BY A MYSTERIOUS RIFT TWO MILES LONG.**

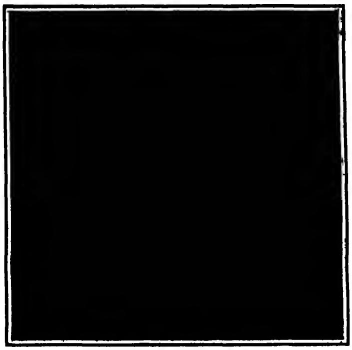
The theater among the rock-cut ruins of Petra.

Ed Der, one of the most remarkable of the temples and tombs of Petra.

hewn equestrian and other statues the whole terminating above in a miniature temple crowned by a huge urn, the entire height being about 65 feet Within is a bare lofty room and some chambers.

A short distance beyond one emerges into the mountain guarded valley in which the city lay, mounds of debris marking the sites of the former homes of the Petrans, the population in the city's palmy days being estimated at from forty to eighty thousand souls The rock hewn structures chiseled in the precipitous cliffs on every side were public buildings and tombs rather than dwellings Just on the left, as the valley is entered is the vast rock-cut theater in semicircular form, capable of holding 3 000 spectators Here the workmanship is Greek. There are thirty-three tiers of seats In this locality are some of the oldest tombs, including detached pylons Many of the oldest tombs were cut away when the theater was hewn out of the mountain side. One of our photographs is of the theater

Standing in this small open valley one sees the façades of tombs and temples of many styles and dimensions with many niches for votive offerings They are at all elevations, many low down on the mountain side, and others high up in the cliffs, with stairways cut in the rock to



The Sik, the entrance to Petra, the impregnable rock-hewn city of antiquity.

reach them While most of them stand out conspicuously others are hidden in the mountain recesses and lateral valleys How eloquent are these silent pylons and obelisks of Edom and Egypt, and these columns and capitals of Greece and Rome! What diverse peoples these tombs have looked down upon when living and given sepulture to when dead! And how many different religions have been represented by ministering priests at these shrines!

One of our photographs is of a tomb or temple in three stories cut out of the mountain wall on the east and showing a succession of similar buildings beyond The façade of this tomb is not like most of the others in imitation of a temple, but of a lordly palace and it has been considerably damaged

On the opposite side of the valley to the west stand the remains of a masonry edifice called by the natives Kasr Farioun (the Castle of Pharaoh), of which we also give a photograph It was a Roman heathen temple

Behind the Kasr Farioun a rock-cut staircase leads up the rugged hill of the Acropolis to the Place of Sacrifice with its altars, pool, and court, all hewn out of the living rock This was a typical holy place, or "high place," of the primitive

(Concluded on page 227)

among the ruins of antiquity. Contrast the stupendous walls of rock which encircle this ancient habitation, and mark how man himself, but an imitator of Nature, has adorned the winding bases of these encircling walls with all the beauty of architecture and art—with temple, tomb, and palace, column, portico, and pediment—while the mountain summits present Nature in her wildest and most savage forms, and among the ineffaceable impressions of your soul will be the memories of this silent, beautiful "rose-red city half as old as time."

PETRA: AN ANCIENT CITY CARVED OUT OF A MOUNTAIN OF SANDSTONE AND ENTERED BY A MYSTERIOUS RIFT TWO MILES LONG.

# AN ELECTRICAL FEVER RECORDER

BY DR. ALFRED GRADENWITZ

Fevor, i e, the rise in blood temperature attending certain maladies is known to be the outcome of a spontaneous reaction on the part of the body against the microbes invading it The opinion is therefore, erroneous that fever in all cases should be acted against in order thus to subdue the morbid state of the patient Nevertheless it is of the highest importance that the physician be kept informed of the variable temperature of the blood

According to present practice temperature readings are taken at regular intervals, say three or four times a day by a sensitive thermometer This practice obviously gives no information as to those oscillations in temperature which may have occurred in the meantime and which, in some cases, it would be desirable to know A process allowing this important factor to be recorded continually and automatically therefore is worthy of universal attention A firm of Berlin constructors, Messrs Siemens & Halske, have recently perfected an apparatus achieving this result

The apparatus is based on a very simple principle viz the alteration in the electrical resistance of platinum wire by variations in temperature It comprises in addition to a coil of platinum wire a Wheatstone bridge and a self recording millivoltmeter

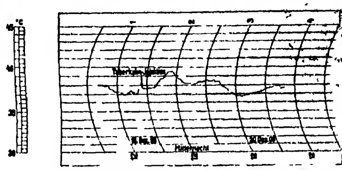
The platinum coil is either introduced into some of the cavities of the body or fixed on the body A double conductor of low resistance connects the coil with the bridge and millivoltmeter, which records any variations in the resistance of the platinum wire and accordingly the temperature of the body

The current required to feed the apparatus is supplied by a small storage battery of four volts, the gradual drop in tension being compensated for in a simple manner by means of a testing and regulating resistance with coarse and fine adjustment As the normal range of the recording apparatus comprises the interval between 30 deg and 45 deg C the curves registered are of sufficient distinctness for any therapeutical and scientific purpose

The electrical fever recorder is constructed in two different types

In the first type, the rotating coil of the millivoltmeter is suspended from a strip of metal, the curve being recorded on a paper tape about 45 meters in length which is moved along by a clockwork at a speed of 20 millimeters per hour The useful width of the tape is 120 millimeters Below the paper tape there moves under the action of a clockwork an inking ribbon, over which oscillates a pointer carrying at its end a runner The position of the pointer is marked by a dot each minute The series of points thus produced forms a distinct curve The clockwork should be wound up once a week, a new paper roll being inserted every three months

The second type comprises a rotary coil located between points, so that the apparatus is insensitive to any moderate oscillations while not requiring accurate horizontal adjustment The registering tape is wound together with a sheet of carbon paper round a drum As in the former apparatus, a style marks time. The apparatus is designed either for a rotation of the drum (about 360 millimeters in periphery) in about 7 days or in 24 hours. The paper tape and carbon should be exchanged after each turn, which is a very easy matter The dropping of the bow occurs,



Record obtained with fever recorder, showing effect of tuberculin ignition

in accordance with the rotation speed of the drum, and takes place either every 12 or every 2 minutes In order to allow for both speeds, the apparatus can be fitted with two drums, exchanged against each other by a simple manipulation The useful width of the paper tape in this case is about 80 millimeters i e, somewhat less than in connection with the former type This is why the one is generally used for accurate, scientific investigations and the latter for ordinary clinical apparatus

AN ELECTRICAL DEVICE WHICH RECORDS A PATIENT'S TEMPERATURE FOR EVERY MINUTE OF THE DAY AND NIGHT.

## Treasure Hunting.

BY GEORGE ETHELBERT WALSH

The United States Hydrographic Bureau and Coast Survey has charts of the Great Lakes and the Atlantic and Pacific coasts which are consulted eagerly by a large class of adventurers and hard, practical men of business and science, who are interested in the recovery of lost wealth through improved methods of deep-sea diving and wrecking. These charts are simple and unimpressive in appearance, and might easily be mistaken for ordinary coast charts with here and there dots to represent submerged reefs or rocks, but to the initiated they tell a whole history of romance and adventure, stories of shipwreck and disaster, tales of lost treasures and of strenuous efforts to recover them. The charts locate the position of sunken wrecks in water so deep that no divers or wreckers have yet succeeded in raising them or unloading from their hulls the wealth of treasure known to exist in them. Some of these wrecks carried down with them gold and silver bullion, which time and salt water cannot destroy, and others are laden with ores of great value, but not so generally prized by the treasure seeker. On the Great Lakes alone the exact positions of wrecks are charted which contain many millions of dollars in bullion and ore. There is no vague uncertainty about these treasures. They were known to exist in the holds of the ships, and no man has yet been able to recover them. The steamer "Pewabic," for instance, which went down in Lake Huron in a storm in 1865 carried with her half a million dollars worth of copper from the Lake Superior mines For three decades expeditions sought to find the wreck, and finally it was located about six miles southeast of Thunder Bay, But the wreck was in such deep water that only a very small fraction of her cargo was ever recovered Here is a submarine copper mine which might tempt the most adventurous soul to risk his life in gaining.

The chart of wrecks on the Great Lakes compiled by the Hydrographic Bureau and Coast Survey shows the relative depth of water and this simple record tells the whole story of why enterprising man has not been able to recover them Divers seeking treasures in sunken vessels have learned that anything which lies much more than 100 feet deep is very difficult, if not absolutely impossible to recover The pressure of the water beyond that depth becomes so great that diving suits are apt to collapse and crush the wearer We know from a study of the charts that hundreds of ships loaded with treasures have sunk in water ranging from 100 to 250 feet in depth and if diving suits could be invented to withstand the enormous water pressure at the lowest depth and enable the diver to work easily, enormous fortunes could be quickly made

The whole history of treasure hunting under the water has been marked by man's futile effort to fight against the pressure at great depths. One hundred feet below the surface of the sea, the pressure is about fifty pounds to the square inch The ordinary diving suit of rubber is inflated by compressed air, which is regulated to the depth reached. Below one hundred feet the diving suit itself frequently collapses. There have been many fatal accidents in attempting to work below the 100-foot mark. For instance, when the steamer "Pewabic" was located in Lake Huron, a diver from Toledo, Ohio, went down to inspect it, and was [illegible] up dead The steamer was in a depth of water approximating 200 feet Two other divers in the next few years met the same fate. In 189[illegible] [illegible]

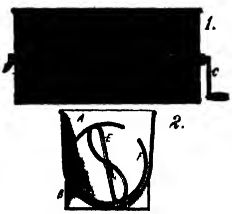
### DOUGH-MIXING APPARATUS.

Pictured in the accompanying engraving is a device adapted more particularly for kneading dough, but which is also applicable for mixing, stirring, or churning any material for household or culinary



DOUGH-MIXING APPARATUS.

purposes. The machine comprises an approximately rectangular receptacle *A* formed, however, with a curved bottom, and an outer casing *B*, which acts as a support for the receptacle. The end walls of this mixing machine are provided with journal bearings, in one of which a crank handle *C* is supported. The other journal consists of a socket *D*, adapted to receive one end of a spirally curved stirrer blade *E*. The opposite end of the stirrer blade is formed with a threaded hub into which an extension of the crank handle axis is screwed. Secured to the stirrer blade at each end are a pair of outwardly projecting arms or curved fingers *F*, the object of which is to reach the material that is not properly stirred and mixed by the main stirrer blade. In use as the crank handle is turned, the fingers tend to feed the material toward the center, so that it is fully acted upon by the main blade. We are informed that in practice this type of stirrer kneads and mixes the dough thoroughly and evenly in a comparatively short time. By holding the stirrer blade and turning the crank in a reverse direction, the latter will be unscrewed from the hub so that both the crank and the stirrer blade may be removed from the receptacle. A patent on this mixing mechanism has been granted to Mr. Sanner E. Ray of McConnellsburg, Pa.

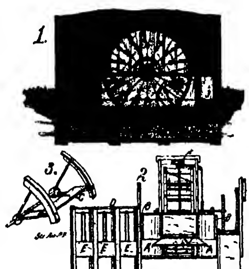
### IMPROVED STEP LADDER.

In the SCIENTIFIC AMERICAN of November 14th, 1908, we published a description of a collapsible step ladder. An improvement upon this form of ladder has recently been patented, which is provided with an upper section that may be removed and replaced with a shorter section, thus reducing the height of the ladder. As shown in the accompanying engraving, the ladder consists of the lower side-rails *A*, connected by means of sleeves with the upper side-rails *B*. The ladder is collapsed by swinging one side against the other, but normally the rails are held apart by means of a diagonal brace, such as shown on the lower section of the ladder. The steps *C* of the ladder are hinged to one of the side-rails as shown in Fig. 3, while at the opposite side they are provided with brackets *D*, in which are slots adapted to engage hinge pins secured in the side-rails *A*. This slot and pin connection provides the necessary play when the ladder is collapsed. The pins on which the steps are hinged lie at right angles to the rails *A*, and in order that the tread surface may be horizontal, the steps are made of a substantially wedge shape, as indicated in the illustrations. The top or platform *E* of the ladder is also hinged to the rails at the points *FF*, which lie on an axis at right angles to the rails *B*. To support the ladder in its normal inclined position, two legs *G* are provided. The legs are connected by the usual links *H* to the rails *A*, and at the upper ends they have extension pieces that are hinged to the rails *B*. When it is desired to shorten the ladder, these extension pieces with the upper rails *B* are withdrawn from their sockets. Then a top piece, such as indicated in Fig. 2, is applied to the ladder, the four short legs of this piece being inserted in the sleeves at the upper ends of the rails *A*. The legs *G* are now made fast to the rails *A* by means of pins *J*, which pass through them and also through the legs of the top piece. To prevent the legs *G* from spreading too far they are retained by means of brace bars *K*. The links *H* in this case are unnecessary and are folded upon themselves, as indicated in Fig. 2. Mr. William J. Blundell, Box 162, Brooklyn, N. Y., is the inventor of this improved step ladder.

IMPROVED STEP LADDER.

### NOVEL CURRENT WHEEL.

A number of advantages are claimed for the wheel illustrated herewith, namely that it does not require the use of dams, it regulates itself to the rise and fall of the stream, uses only the surface current, is equipped with feathering blades, and is provided with means for preventing the parts from freezing fast in cold weather. The water wheel is supported on pontoons, as indicated at *A* in the illustration.



NOVEL CURRENT WHEEL.

The pontoons are connected by means of links or parallel arms *B* to a fixed framework supported on piles driven into the bed of the stream. Fig. 3 shows the construction of the blades used on the wheel. The spokes of the wheel are arranged in two parallel sets which are bifurcated at their outer ends. The blades *C* are hinged to rods connecting the parallel spokes and have free play in the bifurcated portions. This provides a very strong construction, and enables the blades to accommodate themselves to the current so that there is no lifting of the water as in an ordinary water wheel. It will be evident that as the water rises and falls, the wheel will rise and fall with it so that the blades will always extend to a uniform depth into the water. However when the water rises the surface current is apt to be very swift, and it is necessary to reduce the flow past the wheel. This is effected as follows. On the up-stream side of the structure a wing *D* (Fig. 2) is built out diagonally into the stream, so as to direct a large portion of the current between the pontoons and against the water wheel. In this wing are a number of flood gates *E* connected by means of ropes and pulleys to one of the pontoons *A* in such a way that as the water rises, the gates will open, permitting the water to flow through them, and thus cutting down the current that strikes the wheel. To protect the parts in cold weather, a casing is built over the wheel, at the top of which is a suction fan *F*. This is belted to the wheel as shown in Fig. 2. Through a duct *G* a current of warm air is conducted to the interior of the casing, and thence is sucked out of the top of the casing by means of the fan and delivered through the pipe *H* as indicated by the arrow. At the up- and down-stream sides of the casing, hoods *J* are placed, which come close to the surface of the water, and prevent the fan from drawing in cold air instead of the air through the duct *G*. The inventor of this improved water wheel is Mr. W. P. Spooner, Box 3 "The Manse," Carlevale, Saskatchewan, Canada.

### CAR-RETAINING DEVICE FOR RAILWAY CURVES.

In order to insure the safety of cars when rounding curves, and to prevent the car wheel flanges from having undue frictional engagement with the rails, a safety mechanism has recently been invented, which is pictured in the accompanying engraving. It consists of a central rail *A*, that is supported on the ties

METHOD OF RETAINING CARS AT CURVES.

and is strongly braced by means of anchoring devices *B*, which are imbedded in the ground and terminate in plates *C*. The object of these plates is to prevent the anchoring devices from working upward. The illustration shows a portion of a car truck passing over the rail *A*. The axles of the truck are connected by means of auxiliary trusses *D*, below the main trusses, on which blocks *E* are supported. Designed to travel around these blocks *E* are endless chains *F* fitted with rollers. The rollers are pressed by the blocks *E* against the guide rail *A*. As the truck passes round a curve the rollers tend to keep it in place. Ordinarily the forward wheel on the outside of the curve tends to bear against the rail, owing to the fact that it is rigidly connected with its mate on the other side of the curve, and hence it cannot travel faster than the latter. The result is that the flange on the outer wheel is subjected to considerable wear. The centering device here shown, however will prevent the flange of the outer wheel from being unduly pressed against the rails. The guide rail serves to prevent spreading of the rails, and keeps the cars from leaving the track. The inventor is Robert Belden, of Pulga, Cal.

### MASSAGE APPARATUS.

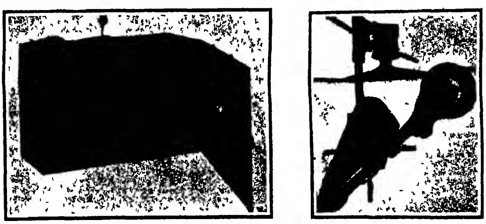
A patent has recently been granted upon a device for securing a vibrator to the hand for application in the operation of massage. The apparatus may be adjustable to adapt it for use by different persons and may be securely clamped to the hand, so as to impart to it the vibratory movement that is used in certain massage treatments. As shown more particularly in Fig. 2, which is a cross section of the device with the vibrator removed, it comprises a padded cushion *A* provided with two plates *B* and *C*, which terminate in horns *E* and *F* that fit the palm of the hand. These horns may be covered with sleeves *K* of rubber if desired. The plate *C* is formed with two lugs, between which is mounted a screw *G* and the latter is provided with a knurled thumbpiece, whereby it may be

MASSAGE APPARATUS.

turned The plate *B* is fitted with a nut *H* that engages the screw, and as the screw is turned the plates are relatively adjusted to bring the horns closer or move them farther apart In this way the device may be clamped on the hand The cushion *A*, however, renders the device comfortable to the operator Projecting from the forward end of the device is a bracket *I*, as indicated in Fig 3, to which the vibrator mechanism is applied Fig 1 shows the preferred form of vibrator, which has a threaded stem that engages a socket in the bracket *I* A locknut *J* serves to make the vibrator fast This type of vibrator is sometimes equipped with a handle as indicated by dotted lines, so that it may be used without attaching it to the hand In such a case however various "applicators" are secured to the threaded stem to take the place of the operator's hand Fig 3 shows another form of vibrator, which is fastened to the bracket by means of screws The inventor of this massage apparatus is John Sabatino, Broadway near Spruce Morris Park New York

### STREET INDICATOR FOR CARS.

The desirability of having the streets announced by means of a conspicuous sign in a street car has often been urged but hitherto efforts in this direction have met with little success Quite recently when a device of this type was about to be adopted on an important city line the objection was raised that it would obstruct and detract from advertisements placed in the cars This objection is overcome in the apparatus shown in the accompanying engravings, which not only announces the streets but also displays advertisements at the same time The inventor hopes that by making the device self paying as well as a convenience to the public, it will meet with better favor than street indicators heretofore devised The prominence of an advertisement placed where all eyes would be concentrated upon it should make this a most valuable advertising medium It is the inventor's idea to use a succession of advertisements so that the display could be changed at each street with the street number The sign display and street indicator is arranged to be hung at any suitable point in the car and immediately after passing a street the mechanism is actuated to announce the next street and display a fresh advertisement. This change is effected by means of contact plates which are secured to the cross wires supporting the trolley wire The contact plate engages a spoke of a wheel, causing the latter to make a quarter turn and momentarily close an electric circuit coming from the wire that supplies current to light the car This momentary impulse actuates a relay in the apparatus contained within the case of the indicator, and by means of a small electric motor the webs on which the street numbers and signs are printed are turned to the required degree Should one of the plates become detached from the cross wire the conductor can operate the indicator by means of a switch When the end of the line is reached the mechanism is reversed so that the streets will be announced consecutively in the reverse direction Should the car cross a different set of streets on the return trip, instead of running the web forward for the whole round and then rewinding at the starting point the web may be arranged to bear the streets of the return trip interspersed with the streets of the forward trip and a shutter may be employed to cover the street names of the first part of the trip, exposing only those of the return trip The inventor of this street indicator is Mr H Aiwins, 214 South 11th Street, St Louis, Mo



STREET INDICATOR FOR CARS.

### AN AUTOMATIC RAILWAY SAFETY SYSTEM.

It is a comparatively simple matter to develop an absolutely automatic railroad system in which the engineer will be entirely dispensed with and the trains will run under electrical control from some central controlling station The reason this has not been done so far, however is because no entirely automatic engine is as safe as one controlled by an engineer The railroads have long recognized the fact that what is needed is not a machine to take the place of the engineer, but one which will act as a check upon the engineer without taking the responsibility from his shoulders—a system that will perform the engineer's work in case of any lapse on his part and make a record of this lapse so that the responsibility for failure on the part of the engineer will be detected A system of this sort was recently installed for purposes of experiment over a short stretch of the Erie Railroad from Newark to South Paterson. The system is quite ingenious in the fact that it gives protection against broken rails as well as collision, and furthermore is provided with telephone connection which enables the engineer to communicate with station houses along the line when the train is brought to a stop for any reason and even while the train is running at full speed The advantages of this telephone system will be appreciated by passengers who can use it to communicate with their homes or to conduct business while en route and the train dispatcher is enabled to come into direct touch with the various units along the line which are under his charge In this system the track is divided into block sections, and the train as it enters each block electrically tests the block ahead to determine whether there is any obstruction on the rails or whether the rails are broken

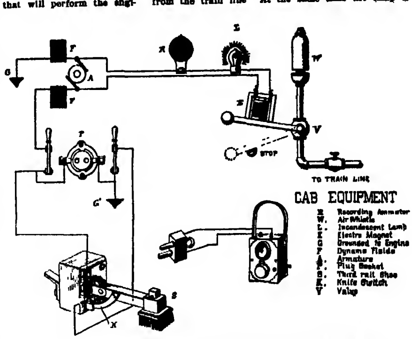


Fig 1 —DIAGRAM OF ELECTRICAL APPARATUS AND CONNECTIONS ON THE CAB OF THE LOCOMOTIVE

The accompanying diagrams illustrate the equipment used On the locomotive there is a shunt wound dynamo driven by a small steam turbine which is supplied with steam from the boiler In series with the armature *A* of this dynamo is an incandescent lamp *L* a recording ammeter *R*, and an electro-magnet *E* which serves normally to hold the arm of valve *V* on the airbrake pipe of the train The fields *F* of the dynamo have their circuit completed through the metal frame of the locomotive. Should the field circuit be interrupted the magnet *E* would be de-energized, permitting the valve *V* to open, thus putting on the brakes and blowing the whistle *W* with air from the train line At the same time the lamp *L* would be extinguished and the ammeter would record the time when the interruption occurred The field circuit is grounded in the locomotive at *G* and *G'* Between the fields and the ground *G'* is a knife switch *K* mounted on a third rail shoe *S* At the side of each block extending for a distance say of fifty feet is a rail *T* (Fig 2) When the shoe *S* engages this rail it is lifted, opening the switch *K* and interrupting the circuit of the fields through the locomotive. However, the circuit of the fields would not open unless there should happen to be a broken rail or a train in the next block

Alongside the track are two lines, *C* and *D*, one of which is connected at intervals with the rails of the track while the other is connected with the third rail sections *T* These lines *C* and *D* run to a station house where the circuit is completed through a switch that may be opened by the engineer in charge of the house whenever he desires to stop the trains along the system under his control The line *C* contains a switch *a* for each block section, which is held in closed position against the tension of a spring by means of an electro-magnet *R'* The latter is connected in series with the rails of the track and is energized by a battery *B* at the opposite end of the block system In case of a breakage in one of the rails, or should a switch be thrown open, the magnet *R'* would be de-energized, permitting the switch *a* to open and thereby break the field circuit of the dynamo on the approaching train with the consequent setting of the brakes as described above The same result would follow if the circuit through the magnet *R* should be short-circuited by a train on the block At *P* (Fig 1) is a plug socket adapted to receive the telephone plug connection. The telephone circuit is completed past the switches *a* through a coil *R²* This resistance permits the passage of the alternating current of the magneto and telephone, but prevents the passage of the direct current to the dynamo so that telephonic communication is not interrupted by the block system.

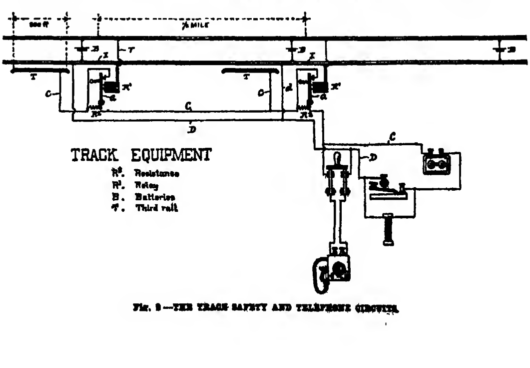

Fig. 2—THE TRACK SAFETY AND TELEPHONE CIRCUITS.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

BUTTON-FASTENER.—H. G. C. Hoennig, New York, N. Y. The fastener quickly fastens a button in place on a garment by the use of a pin engaging and holding the button and adapted to be passed through the cloth of the garment, the pin engaging a retaining device on the back of the garment and preferably formed of a plate having a head and neck for engagement by the U-shaped end of the pin to fasten the pin and plate together.

### Electrical Devices.

SWITCH-PLUG.—P. C. Ewing, Little Rock, Ark. In this improved construction, the inventor permanently connects the cord to the plug, so that the cord extends from the plug at approximately an angle of ninety degrees. The plug remains in a horizontal position when in use and out of use, and the movement of the plug from one position to the other, does not cause binding of the cord at its point of connection with the plug.

### Of Interest to Farmers.

GRADER.—J. W. Beasley, Modesto, Cal. By the use of this mechanism the earth is plowed and delivered to an elevator and distributer, plowed dirt is delivered at each side of the machine alternately so that it may be distributed or received in a conveyor for removal, the delivery being manually controlled, the receiving drum guides the delivery belts and forms a driving member therefor and delivers the dirt from the interior of the drum upon the belts and the manually-operated controls command the operating mechanism.

### Of General Interest.

WALL-MOLD.—E. W. Collins, Fort Dodge, Iowa. This invention pertains to cement or concrete walls, and its object is to provide a new and improved wall mold for use in building a monolithic concrete wall, with or without air spaces and with a facing of a different, finer material to enhance the appearance of the wall.

MATCH CASE.—R. Epstein, New York, N. Y. This invention relates to match cases, particularly to such as are adapted to be carried in the pocket. The device is especially to be used as a case for matches which are permanently attached to a card-board sheet or holder, and which are adapted to be torn off one by one when used. These matches are attached at their lower edges to the lower edge of a flap, and this projects in a direction in which the heads of the matches lie.

WALL.—M. B. Ensminger and J. W. Shaffer, Fostoria, Ohio. In the present patent the invention has reference to improvements in walls, and it has for its object the provision of a construction whereby there is an air-space between the blocks forming the wall and the plaster-boards or laths, without its being necessary to veneer the blocks.

FIRE-ESCAPE LADDER.—W. A. Farmer, Arcade, N. Y. This collapsible ladder may be conveniently stored adjacent to a window, and is adapted to be readily adjusted out of the window in case of a fire. It is strong, of light weight, easily manipulated, and will automatically space itself from the side of the building so as to leave room on the rungs for the hands and feet of the user.

VAGINAL SYRINGE.—G. Katzenberger, Chicago, Ill. This invention is more especially designed for use in spraying medicinal powders onto the diseased parts and arranged to permit conveniently charging the powder container of the syringe with powder, to insure a proper spraying and spreading of the powder and to provide an escape for the air pressure from the parts.

ORE SEPARATOR.—G. W. Kunkel, King City, Mo. When the toothed cam wheels rotate the feed end of the screen frame will have imparted thereto a series of rapid vertical impulses, while the frame will be vibrated rapidly in a horizontal plane and in a longitudinal direction by one of the cam wheels, the wheels moving the frame one direction and springs in the opposite. As the ore is fed onto the feed end of the screen a jumping motion is imparted thereto, tending to move coarser particles above the finer, permitting them to pass through the screen, while the ore travels longitudinally of the screen by action of the cam wheels.

BEER TAPPER.—W. W. Frisholm, Leadville, Col. The invention relates to that type of tapper in which the valve is fitted in the bushing of the bung hole and the patentee provides a novel arrangement of valve casing as securing devices and passages with a view of facilitating the operation and the action of the tapper in controlling the fluid to be drawn.

DRINK-SHAKER.—J. Heinrichs, New York, N. Y. The invention relates to drink mixers, and its object is to provide a shaker, more especially designed for use in making cocktails, milk punches and like drinks, and arranged to allow convenient mixing and cooling of the ingredients and straining and pouring of the drink into a glass.

ORE-MILL.—T. C. Hinton, Shawnee, Okla. In this case the invention is an improved mill for reducing ores containing precious metals, particularly quartz ores of both hard and soft varieties. It combines the functions of a stamp mill and a grinder, in that it is adapted to hammer the ore so as to break it into small pieces and then grind and crush it into smaller particles.

HOLDER AND MEASURING DEVICE FOR GRANULAR MATERIAL.—A. A. Hautt, Chicago, Ill. In the present patent the purpose of the inventor is to provide a receptacle for granular material such as tea, and combine therewith novel, simple, and convenient means for measuring and discharging a quantity of the contents of the receptacle into a vessel for use.

ADJUSTABLE CURVE-RULER.—C. O. Harper, Omaha, Neb. The invention consists of an abscissa ruler or straight edge, a spring ruler, and ordinate rulers adjustable laterally and arranged at the opposite end portions and at an intermediate point of the spring ruler, and two outer ordinate rulers having pivotal portions connecting them to and adjustable along the length of the spring ruler.

PAPER-BAG HOLDER.—J. W. Dunnigan, Altoona, Pa. The object of the invention is to provide a cheap and serviceable rotating paper bag holder which will furnish a maximum of separate holders in a minimum of space and wherein each size of bag will be in a separate bunch and may be easily got at and removed. It is the only rotating bag holder ever devised and being triangular in shape, gives three sides that revolve in the space of one.

VAPOR EXTRACTOR FOR USE IN TREATING WHISKY BARRELS.—B. H. Hubbert, Highlandtown, Md. The invention is a vapor extractor for use in treating whisky barrels, and in operation, steam or other medium may be introduced through the inlet pipe to operate upon the interior of the barrel, and then be discharged through the ports and the body and outlet in the operation of the apparatus.

WATER-GLASS-GAGE CUTTER.—F. Blouart, Butte, Mont. This instrument cuts glass tubing from the inside thereof, to form water gage columns, the cutter may be set to sever an article to the size desired. It is adapted to cut the inside surface of a tube, having means for exerting an outward pressure upon the point of operation and the parts of the implement are held and returned to their normal position by automatic means.

### Hardware and Tools.

LAWN SPRINKLER.—G. H. Choate, Hailey, Idaho. This invention provides a sprinkler which may be placed beside a foot-path for a house to irrigate the lawn without wetting the walk or house, provides one which may be secured in position by the operator without necessitating the suspension of the flow, and one of a structure diminutive and easily handled.

STEP-LADDER.—W. J. Blundell, New York, N. Y. This invention relates more particularly to that type of ladder disclosed in a prior patent granted to Mr. Blundell. One object of the present invention is to so construct the side rails and legs of the ladder that each may be separated into two sections, and one of the sections replaced by a shorter section to produce a step-ladder of shorter length.

CLASP.—A. O. Hoyland, Aurora, Neb. In the construction of this clasp the applicant provides a pivoted jaw having a spring tongue at its pivot end for holding the jaw closed and at the opposite end a cam device is provided which co-acts to maintain the tongue in its holding position.

BOLT AND NUT LOCK.—C. H. Ferguson, Jersey City, N. J. More particularly the invention refers to a nut lock in which there is employed a plate or washer having a yoke which may be bent up to partially inclose the nut, or at least engage with a plurality of sides of the latter. The plate is so formed that it is automatically held against rotation and serves not only to lock the nut in place but may also lock either the bolt or a second nut, or all three.

### Heating and Lighting.

SAFETY PLUG.—E. H. Bastion, Fairbury, Ill. The object here is to provide a plug, for convenient attachment to the crown sheet, fire sheet, or other part of a boiler, to indicate danger in case of low water level, and arranged to prevent the fusible material from being dislodged or blown out of the plug body by pressure in the boiler to insure an even heating of the fusible metal core, to prevent the plug body from being clogged up by sediment, and to provide a ready flow of molten metal out of the body of the plug and permit free escape of pressure to relieve the boiler of undue strain.

TANK HEATER.—W. Tinker, Anamoose, N. D. The aim of this inventor is to provide a means for heating the water in a tank or reservoir, the heater to be partially submerged in the water and having means for supplying fuel, and for permitting the removal of ashes, and the entrance of sufficient air to properly consume the fuel.

### Household Utilities.

CRADLE.—L. Vargas, New York, N. Y. This improvement is in motor-actuated cradles, and has in view a cradle supported to oscillate about an approximately central vertical axis, the cradle in its preferred construction having an annular track on the under side which is arranged to be alternately engaged at opposite sides by wheels or segmental gears driven by the motor.

GARBAGE-CAN.—W. R. Osborn, Clarksburg, W. Va. The main purpose of the invention is to provide a garbage can which has a hinged cover pivoted in such a manner that it may be raised by foot pressure, thereby permitting the use of both hands in transmitting the garbage into or removing the garbage from the receptacle.

### Machines and Mechanical Devices.

BOTTLE-WASHER.—R. J. Phelps, Callicoon, N. Y. This invention refers to bottle washers and fillers, and the object of the invention is to provide an apparatus of simple construction, in which a number of bottles can be rapidly washed and refilled and when the bottles in the frame are filled it descends and the bottles can be removed for corking.

BUILDING BLOCK MOLD.—C. J. T. Combs, Waldwick, N. J. This mold is adapted to make blocks of different sizes. The invention contemplates an arrangement in which the sides or walls of the mold may be moved outwardly so as to enlarge the mold, and the mechanism includes means for moving some of the walls in unison so that the cores for the block are advanced automatically into position.

PIANO-SWELL.—Sarah W. Clark, New York, N. Y. It has been found that the movement of the lid by mechanism concealed from the audience often operated to distract its attention from the music and constituted a disturbing element. In the present patent the inventor avoids this objection by providing means within the casing of the instrument and entirely concealed from the audience, for controlling the volume of sound. Her new mechanism is separate and distinct from the lid of the instrument.

LIQUID-EJECTING APPARATUS.—H. K. Smith, Union, S. C. In the present patent the invention is an improvement in apparatus for dispensing liquids adapted for use in ejecting soda water syrups and mineral waters and other liquids. The fountain construction in this apparatus forms the subject of a separate application for patent which Mr. Smith is about to file.

LIQUID-DISPENSING APPARATUS.—H. K. Smith, Union, S. C. In this case the invention is an improvement in apparatus for dispensing liquids adapted for use in dispensing soda water syrups and mineral waters and other liquids. The present patent is a divisional application of Mr. Smith's prior application filed in the United States Patent Office.

CABLE-CLAMP.—C. A. Butler, Bartlesville, Okla. In the present patent the object of the invention is the provision of a new and improved cable clamp, more especially designed for use on well-drilling tools and other devices, and arranged to securely clamp the cable and to positively hold the same against slipping.

METER BOX.—L. P. Andrews, Sedalia, Mo. The object of this inventor is to provide a box, which serves as a protection for the meter incased therein which can be easily opened to permit the meter to be read, the closure of which can be locked securely in place to prevent accidental or unauthorized opening thereof, and which is substantially water tight.

### Prime Movers and Their Accessories.

CARBURETER.—P. J. Darby, New York, N. Y. This invention has reference to carbureters such as used in connection with gas engines. The object of the improvement is to produce a carbureter having an improved construction which operates to draw the air in a concentrated current directly across the fuel opening from the admission valve.

### Railways and Their Accessories.

SPARK ARRESTER AND DRAFT REGULATOR FOR LOCOMOTIVES.—R. J. Haack, Tanta, Egypt. The aim in this patent is to provide an attachment for distributing products of combustion more evenly, or causing them to pass through the lower flues as well as the upper and also for arresting the sparks, which under other circumstances, would reach the smokestack and be discharged therefrom. It effects considerable economy in coal consumption.

RAILWAY CROSSING.—A. H. Havard, Urbana, Ill. In this instance the invention has reference to railroad crossings and it has for an object the provision of a crossing for railroads, adapted to minimize the amount of noise occasioned when a train is passing over the crossing, and the said crossing being safe and efficient.

### Pertaining to Vehicles.

DUST-PROOF SELF-OILER FOR AXLES.—J. J. McGoran, New York, N. Y. This invention relates to wheels such as carried by carts and wagons. The object of the improvement is the production of a wheel having an axle box which will be self-oiling and substantially dust proof. The absorbent material placed in the dust chamber is preferably formed of lamp wick or similar woven material.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th, 1909, or will be sent by mail on request.

(12206) E. J. B. asks: A said that a bullet shot in the air (the carrying power of the rifle being one mile), after reaching its limit will return to the earth just the same as if you were a mile in the air and shot a bullet from the same rifle toward the earth. B says that the bullet shot from same rifle one mile toward the earth will reach the earth sooner than the bullet dropped from a mile in the air. A. If a bullet is shot from a rifle so that it rises a mile into the air it will be for an instant at rest at a point a mile above the earth, and neither rising nor falling. It will immediately begin to fall as if from rest, and fall a mile to the earth. It will strike the earth with the velocity acquired by a fall of one mile through the air. This will not be the same as free fall since the air will retard its fall somewhat. If a rifle at a height of one mile above the earth discharges a bullet vertically toward the earth, the bullet will have two forces acting upon it, the force of the powder and the force of gravity, both urging it downward and its velocity will be that given by the sum of the two forces. It will reach the earth in much less time than would be required for a falling ball. A is wrong and B is right.

(12207) W. I. S. asks: Please advise when the twentieth century began, whether on the first day of January 1900 or January 1, 1901. A. The twentieth century began at midnight of the morning of January 1st, 1901. The year 1900 was the hundredth year of the nineteenth century. Begin and count from one and you will find that 100 is the last number of the first hundred, so 1900 is the last number of the nineteen hundredth of numbers or centuries.

(12208) G. P. asks: Will you kindly inform me as to the construction of the siren whistles as used on the United States navy boats? Some tell me they consist of a disk having slits cut between the center and circumference which is caused to whirl by steam pressure; others say not. While not a yearly subscriber I get your valuable paper from the newsstand and would very much appreciate a reply to this inquiry. A. Sirens are made very much as you describe, although round holes are more frequent in the larger sizes than slits. There are two plates, the lower stationary and the upper revolving. In the lower the holes are vertical and in the upper they are inclined all at the same angle, but the lower end of the holes in the upper plate register with those in the lower when still. When steam is turned on the upper plate is revolved exactly as a windmill is blown round, and the faster it turns the more frequently the holes register, cutting off and passing the steam alternately. This causes vibrations of shorter and shorter period to be applied to the bell of the whistle, giving a higher and higher note, till the steam is cut off when the note descends in the same way.

(12209) T. A. G. asks: Can a circle be squared? If so how can it be done? I have read in papers about people working on it for years and could not do it. Is it only a joke or are those people in my class and don't know how to count? What I mean is, to square a circle of any size down to the very finest square the fingers can make. A. A square of exactly the same area as that of a given circle cannot be constructed. In other words the side of a square whose area shall be equal to that of a given circle cannot be found by the use of drawing instruments. A number of approximate solutions have been made. The area of a circle is found by multiplying the circumference by half the radius. The circumference is found by multiplying the diameter by the number 3.14159265358 etc., a number which never comes to an end and which has been computed to a very large number of decimal places. Now since the circumference cannot be exactly found the area cannot be exactly found and the side of the equivalent square cannot be exactly found.

(12210) C. W. asks: I would like very much to have you explain how it is possible for an ice boat to go faster than the wind. I am quite sure it does this though I have not the instruments to prove it. If it does it appears to be contrary to the laws of conservation of energy. A. An ice boat sailing before the wind does not go swifter than the wind. That is impossible even when we take account of the small friction of ice. It will retard the boat somewhat. But when the boat sails near the wind the line followed by the boat is longer than the distance the wind travels while pushing the boat a distance equal to its length and so the boat moves farther than the wind moves in the same time. You will find the point discussed in our Supplement, No. 214.

## NEW BOOKS, ETC.

**The Gas Turbine. Progress in the Design and Construction of Turbines Operated by Gases of Combustion. By Henry Harrison Suplee, B. Sc. Philadelphia: J. B. Lippincott Company. Pp. 262. Amply illustrated.**

In view of the rapid advancement in the development of the gas turbine, the literature upon this important subject must be regarded as quite inadequate. Hence the value of the present work by Mr. Suplee, whose name is synonymous with very thorough, accurate, and illuminative work in literature of this character. Although the gas turbine was one of the earlier forms of the combustion motor, the high temperature and high relative speed involved have rendered the mechanical problems connected with centrifugal action so difficult of solution that progress has been slow compared with that in the production of the steam turbine. Nevertheless, some very effective experimental work, to say nothing of theoretical investigation, has been done during the past few years by English, French, German, and American scientists. Unfortunately, most of the information regarding this work is in a form unavailable for the practical engineer and investigator. The theoretical discussions are to be found chiefly in the transactions of professional societies, and the practical work has been done behind closed doors. In the present work Mr. Suplee has gathered under one cover the most important papers which have appeared upon the subject of the gas turbine, together with some account of the work done in America. To this has been added such information upon actual experimental machines as could be secured. The various papers are preceded by an historical chapter of great interest, which throws much light upon the early history of the gas turbine, which the reader will be surprised to learn dates back in its primitive form to the mediæval "smoke jack," which has been attributed to Leonardo da Vinci. Of equal historical interest is the information that Barber in a British patent of 1791 completely anticipated nearly all the most recent developments in gas turbine practice. The illustrations, chiefly line cuts, are numerous, and the tables and diagrams afford just that exact information of which the inventor and experimentalist is in need. We commend this work as a most valuable addition to the too scanty literature upon this subject.

**Paints for Steel Structures. By Houston Lowe. New York: John Wiley & Sons, 1910. 16mo., 109 pp. Price, $1.**

About thirty years ago practice in the making of linseed oil, varnishes, japans, and colors first brought the writer into daily contact with questions regarding the manipulation of paint, its properties, and the results of the various operations to which it was subjected. Painters, engineers, architects, builders, and constructors have since been continuously asking questions whose answers involved thought and experiment. At one time paint making was an art, then it became a trick, now it is a science. This little handbook is written by a paint maker, and is the direct result of study recently given to the manufacture and properties of structural steel and the use of paint in its preservation. During the ten years which have passed since the first edition of this book the author has continued his observations, experiments, and tests on a more elaborate scale than ever before, and with careful attention to every point needing consideration. The book appears to be a most valuable one.

**American Annual of Photography. New York: George Murphy, Incorporated, publisher, 1910. 8vo.; 328 pp. Price, 75 cents in paper, $1.25 in cloth; postage 15 and 20 cents extra.**

This volume, which is No. 24, is edited by John A. Tennant. It is filled as usual with valuable photographic hints, and is beautifully illustrated. It will be warmly received by all amateurs.

**Vehicles of the Air. By Victor Lougheed. Chicago: Reilly & Britton, 1910. 8vo.; pp. 479; 270 illustrations and diagrams. Price, $2.75 postpaid.**

This book fully meets the demand for a popular semi-technical treatise on mechanical flight. Its author is above all else a thoroughly practical man, and one who has had wide experience with automobiles and their motors. As a result of this, the chapters of his book on power plants and transmission mechanism are very illuminating. The various kinds of lighter-than-air and heavier-than-air flying craft are illustrated and described in detail, and the whys and wherefores of different forms of construction are made known. Many details of aeroplane construction are given in a clear and concise manner and illustrated by diagrams. Fifteen leading aeroplanes are described in detail, most of them with the aid of scale drawings and handsome large half-tone engravings. The author discusses the work of the pioneers of aerial flight, and so thoroughly does he go into some of the burning questions of the hour, such as wing warping and the like, that he publishes the complete patent specifications of Lilienthal, Chanute, Mouillard, Wright, and Montgomery. The last-named gentleman's paper on "Principles in Wing Formation and the Phenomenon of Soaring," which was prepared for the Aeronautical Congress in 1907 at the suggestion of a [illegible] in the Scientific American Supplement two years [illegible], is also printed in full and will be found extremely interesting. A very complete list of flights made up to November, 1909, is one of the many excellent features of this work.

THE ROCK-HEWN CITY OF PETRA.

(Concluded from page 221.)

peoples of the land. These "high places" were the subjects of many warnings to the children of Israel. There are other high places in the vicinity of Petra.

Still another interesting ruin is of the so-called Ed-Deir (the convent), and is reached by an hour's hard climbing along ravines and up rock-hewn staircases, to the northwest of Kasr Farioun. Passing the striking Tomb of the Lions, we reach at last the high plateau on which stands Ed-Deir. It is nearly 150 feet long and almost as high, being similar to the Khasneh, having its double rows of six columns each, but widened by corner-pilasters on both sides and on both stories. On this plateau there are several places of sacrifice and a fine view of Mount Hor to the southwest.

The early history of Petra is hidden in the mists of remote antiquity. It was probably the capital of Edom. Its first mention is in sacred history in II Kings 14 7, which records its conquest by Amaziah in the ninth century B. C. From Is. 16 1, we learn that it was then, about 700 B. C., held by Moab. It is evidently referred to in several prophetic denunciations whose fulfilment has been most literal. About 300 B. C. it had come into possession of the warlike Nabataeans, descendants of Nebaioth, the eldest son of Ishmael, who made it their capital, and it was known to the Greeks as Petra. Strabo, the Greek traveler and historian, describes it at the end of the last century B. C., as also did Pliny, the Roman writer, in the first century of our era. In A. D. 60 Aretas IV, King of Petra, had extended his conquests to Damascus, and is referred to by St. Paul in II Cor. 11 32. In 105 A. D., in the reign of Trajan, it passed under Roman rule. Ecclesiastical historians in about the fourth century mention it as a Christian metropolis. It continued populous and prosperous as a trade depot until about the beginning of the fourth century, when the caravan routes from the north, which had for so many centuries led past its arched portal to the Red Sea, were diverted to the Persian Gulf. After this it rapidly declined, and it is not heard of again until about A. D. 536. Even its very existence and site were forgotten until it was visited and identified by Seetzen in 1807, and explored and described by Burckhardt in 1812, the latter gaining access to it as he also did to Mecca, in the disguise of a Moslem pilgrim.

Treasure Hunting.

(Continued from page 223.)

a noted Lake diver, devised a diving suit strengthened with metal rings to support the rubber against the enormous water pressure. In this suit Pelky made a successful exploration of the ship, but on his second descent his suit collapsed and he was hauled up dead.

Even this fatal accident did not deter wreckers from planning further attempts on the immense cargo of copper at the bottom of the lake. A famous diver of Duluth, Minn., M. F. Chalk by name, was invited to go down, and to tempt him to make the venture $2,500 were offered him before he went down, and a written promise that he would get one-half the net returns from the wreck. In addition to this his life was to be insured for $20,000 for the benefit of his family. But after making an examination of the location and the depth of the water, Chalk refused this flattering offer.

Many accounts of great depths to which divers have descended to inspect wrecks and help to recover treasures must be accepted with a little grain of salt. For instance, John Haggerty, who went down to inspect the steamship "Oregon," wrecked off Fire Island, was generally reported to have reached a depth of 185 feet. But to disprove this the hydrographic charts show that the depth of water where the steamer sank was only 1[illegible] feet. Other remarkable diving feats

(Continued on page 235.)

*(Continued from page 227)*

must also be accepted with a slight allowance for exaggeration

In recent years deep-water salvage of treasure ships has excited the cupidity of divers adventurers, and business men There is altogether too much wealth lost under the water to suit us. Here is what an expert diver and wrecker has to say on the subject

'Within fifty miles of Sandy Hook there is wealth enough sunk in the ocean sand to stock the United States Treasury All the private treasure ever buried in the earth would be a trifle by the side of it The bottoms of both the Atlantic and Pacific Oceans are vast treasure beds. The man who can devise a means of traversing the ocean bottom might rival Rockefeller A vast amount of treasure is as accurately located as the banks of Wall Street Any experienced diver can take you to a chart and lay his fingers on any one of twenty spots and say 'Go to longitude so-and-so in a latitude definable within fifty feet, dive deep and bring up a fortune Only you can t dive deep enough A great deal of this treasure is the deposit of recent years Still more went down before the days of ocean liners At one time specie was transported in men-of-war Gold dust and diamonds were shipped from mines on rickety schooners for want of better craft '

In twenty years there were nearly five thousand wrecks on the Great Lakes. Of these over one-fifth or approximately one thousand, were total losses The total cargo losses on these wrecks are estimated at $12,000,000 and much of it is in indestructible form of property These tragedies on the lakes go back to 1680, when La Salle's ship, the 'Griffon," disappeared in Lake Huron with $12,000 in coin Besides the 'Pewabic" which went down with half a million dollars' worth of copper, the steamers 'R. G Coburn" and City of Detroit' were lost off Saginaw Bay in 1871 and 1873, with cargoes of copper aboard worth at least $50 000 each None of this treasure has been recovered The steamer "William Home," which sunk in 1895 off Swishwah Point, Lake Michigan, carried to the bottom $20,000 worth of steel billets, and the steamer "Clarion ' lost in 1851 between Cleveland and Detroit, carried a deck load of new locomotives to the bottom. Iron and coal cargoes have been distributed freely over the bottom of the Great Lakes and some day the miners of these ores equipped with improved diving dress, may recover good-sized fortunes from the bottom of the lakes.

Lake Huron is considered the greatest scene of treasure hunting, and it is commonly spoken of in the lumber camps as 'The Lake of Sunken Treasures ' The reason for this is that back in the early lumbering days large sums of money were shipped to the numerous lumber camps in small vessels, and literally dozens of these were lost. All of this money lies somewhere at the bottom of the lake for the treasure hunter to find

Among the many important wrecks of treasure ships which are partially or exactly located on the charts of the government, mention should be made of the Pacific Mail steamship 'Golden Gate,' sunk near Manzanilla, Mexico with $600,000 in gold coin and bullion and the Klondike steamer "Islander," sunk off Douglas Island, Alaska with $375 000 in gold dust The greatest prize of all sunken treasures—if all is true which history records—is the Spanish galleon which went down five miles off Lizard Point on the Cornish coast in 1784 with $85,000 000 in gold The Spanish flagship "San Pedro was another rich prize, carrying to the bottom of Cumana Bay, Venezuela, $2 000 000 and the ship "Central American" went down off Havana with a similar amount in gold The steamship "Lexington" which went down in Long Island Sound was reported to have contained $300 000 in specie

The record of these sunken treasure

(Concluded from page 228)

ships along our two coasts and Great Lakes could be extended indefinitely. Some of the treasure has been recovered, such as the boxes of gold lost in the Spanish steamship Mercedes, sunk near the Canary Islands, but in most cases very little if any of the money has ever been brought up by divers.

There have been strenuous efforts made to salvage these known wrecks, and inventors have been busy for half a century devising means of getting at the wealth lost under the water. The aluminium diving suit that resembles ancient armor, with articulated joints at the shoulders, knees and hips, is one of the new inventions designed to make deep-sea diving practical. With this armored suit divers expect to reach a depth of 250 feet without experiencing any great difficulty in resisting the pressure. The pressure of water on the joints of this armored diving dress was so great that ball bearings of harder material than aluminium were found necessary. The aluminium suit protects the diver from the water pressure, and at great depths the armor is so light in weight that a man can walk around easily with it on. In addition to the articulated armor suit the diver is provided with an intricate system of hooks operated by the hands from the inside, so that his work can be performed without exposing any part of the body. The diver is provided with a telephone, a headlight and an apparatus which registers the amount of air sent down through the breathing tube. The wreckers from above can thus tell at all times the condition of the diver.

The science of salvage as conducted by modern wrecking companies in the raising of ships is a matter totally outside of that of raising sunken treasures. The ships laden with their treasures have for the most part been in the water so long that to raise them by compressed air would be impossible. Their rotten decks and timbers would explode and burst asunder long before sufficient air could be pumped into them to raise them from their muddy beds. Consequently the salvage of treasure-laden ships of the past is purely a matter of deep-sea diving. The diver who can go down the deepest and remain there the longest is the one who will receive the gratost reward for his venture.

Even with a diving dress that will protect the diver from the great water pressure, and with all the equipments of lights, hooks, telephone and air-registering device, the man who descends to great depths must encounter other perils of a blood-curdling nature. Rotting decks and timbers may set a trap for him through which he may fall to his death. Long tunnels through deserted cabins and hulls filled with floating objects may tangle up his tube through which fresh air reaches him, and within a space of a few minutes death by suffocation follows. There are grisly wolves of the ocean to encounter in some seas, veritable man-eating sharks and other death-dealing monsters of the deep. A single false step may precipitate death, and yet time is precious and speed of action must be attained. Dark lonesome hulls must be examined, intricate cabins broken into, and not infrequently the golden treasures must be dug out of the sand and mud into which they have buried themselves. Altogether it is a grewsome experience, and one that keeps the strongest man's nerves a-tingle. There are few sights which can equal the interior of a sunken ship whose ribs have been rotting beneath the ocean's waves for a century or more. Some timbers are so well preserved that they cannot be broken easily with an ax, and others so decayed that a diver can thrust a hand through them as easily as a knife goes through cheese.

The diver earns all the wealth that he gets from a sunken treasure ship, and only the hardest and most expert divers will undertake this work. They prefer as a rule to stick to ordinary wrecking in water forty to fifty feet deep.

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO. Inc.

## PATENTS FOR SALE

FOR SALE, Outright or on Royalty.—Match Box. U. S. Patent No. 944,786. By pressure of finger it lights, presents and drops match without opening box. For full particulars address J. J. Willingham, la Bucareli No. 56, Mexico City, Mexico.

Inquiry No. 9015. For manufacturers of "Wyatt's Electro-Catalytic Sparking Plug."

FOR SALE. U. S. patent rights to highest bonafide bidder, April 2, 1910, telephone muffler. Telephone booths no longer necessary. See descriptive notice in February 26th issue. W. H. Plumb, 323 Lexington Ave., N. Y.

Inquiry No. 9007. Wanted the manufacturers of the Van Winkle, Woods & Sons, and the Weber power meters.

## HELP WANTED

WANTED young man technical graduate in physics and chemistry; knowledge of optics also desirable. Splendid opening and opportunity for right man. Address M. M. Co., Box 773, N. Y.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

## FOR SALE

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads 8 to 40 in. Price only $45.00. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9019. Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Reuscher process.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9042.—Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into skeins.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9019.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

Inquiry No. 9016. Wanted the address of the manufacturers of Cycle Ball Bearing Suspenders.

Inquiry No. 9038. Wanted the address of the Chipman Electric Purifying Co.

Inquiry No. 9040.—Wanted the address of Parney Safety Razor Co.

Inquiry No. 9052.—Wanted, address of firms who install plants to manufacture nitrogen.

Inquiry No. 9055. Wanted address of parties interested in Log Cleaning Machines.

Inquiry No. 9060. Wanted to buy machinery to manufacture seed corn racks.

Inquiry No. 9066. Wanted complete outfit for export for making rice flakes and wheat-flakes.

Inquiry No. 9064.—Wanted to buy machinery for manufacturing chewing gum, such as rolling, cutting or wrapping machinery.

Inquiry No. 9069.—For the address of firms making chain cloth, something like ladies' purses are made of.

Inquiry No. 9071.—Wanted, the address of parties making moulds for large concrete vases for flower pots.

Inquiry No. 9072. Wanted machinery for making fine chains, such as used by jewelers, etc.

Inquiry No. 9073. Wanted, machinery to manufacture cocoanut oil; also the crude material.

Inquiry No. 9074. Wanted to buy old model locomotives or steamboats, such as were exhibited with nickel in the-slot attachments in ferry houses, etc.

Inquiry No. 9075.—Wanted to buy small weather vanes such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted the address of parties in Canada who could make a safety razor.

Inquiry No. 9077.—Wanted the address of manufacturers that make small articles of wood, such as checker boards, etc.

Inquiry No. 9078.—Wanted the address of manufacturers of sewer pipe made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9079.—Wanted, parties to make a special steel plate rolled for "angle bars," in large quantities.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9081. Wanted, manufacturers of a mixing machine to mix powdered and fluid ingredients to a thin dough; also molds to put such dough in to dry; the size to be about 3½ inches long, 2¼ inches wide and 1¼ inches high, making the form of a cake like sapolio.

Inquiry No. 9082. Wanted, the address of firms manufacturing small beer brewing plants, from 25 to 100 gallons a day.

Inquiry No. 9084.—Wanted, the address of manufacturers of Irwin portable bath tubs.

Inquiry No. 9085.—Wanted to buy longitudinal hollow perforated tubing.

Inquiry No. 9086.—Wanted, to buy a pine wood peeler.

Inquiry No. 9087.—Wanted a machine for hard coating back saw blades; also a machine for setting same when they have been toothed.

Inquiry No. 9088.—Wanted, the address of manufacturers of family sized peanut pulverizers for making peanut butter.

Inquiry No. 9089. Wanted, the address of manufacturers of galvanized steel perforated hollow tubing.

Inquiry No. 9090.—Wanted manufacturers of suspender and supporters supplies, also patent adjustable bachelor buttons.

Inquiry No. 9091.—Wanted parties to manufacture a new patented clothes hanger.

Inquiry No. 9092.—Wanted, the address of some firms who manufacture permanent lamp wicks.

Inquiry No. 9093.—Wanted, manufacturers of metal specialties and novelties.

Inquiry No. 9094. Wanted, address of The Thomas Arithometer Company, also Burkhart Arithometer Company.

Inquiry No. 9095. Wanted, name and address of the manufacturer of the duplex revolving pencil sharpener.

Inquiry No. 9096.—Wanted, the address of manufacturers of spiral welded pipes, possessing great strength.

Inquiry No. 9097.—Wanted, address of makers of impulse water wheels.

Inquiry No. 9098.—Wanted name and address of the manufacturers of the ozonizer.

Inquiry No. 9099.—Wanted address of manufacturers of machinery for making wire cables.

Inquiry No. 9100. Wanted addresses of manufacturers of a dip or magnetic needle for exploring for iron ore.

## REMINDER BULLETIN

## A Boon to the Busy Man

The use of the most modern type of speed-making locomotives, coupled up to the best type of equipment and guided by the most vigilant management makes railroad travel secure and prompt.

The time of a busy man is one of his assets. It means either gain or loss to him.

The certainty of figuring his time in transit to the exact hour relieves his engagement list from entanglement.

The telephone may make the engagement, the train will keep it.

**The Pennsylvania Special** follows up the telephone message. It brings the two ends of the wire together and consummates the meeting between working hours.

The man with business connections in New York and Chicago can lose no time by traveling on the **Pennsylvania Special**. It runs while the desks are closed.

**Pennsylvania Special** (18 hours between New York and Chicago) leaves New York 3·55 p. m. Downtown Tube 4·05 p. m. and arrives Chicago 8·55 a. m.

Over five hours for business to 2:45 p. m. when it leaves Chicago for the East and arrives in New York next morning (Breakfast on the train) at 9:45 a. m.

# Industrial Alcohol

## Its Manufacture and Uses

By JOHN K. BRACHVOGEL, M.E.

*Size 6¼ x 9¼ inches. 528 pages. 107 illustrations. Price $4.00, postpaid.*

A PRACTICAL treatise based on Dr. Max Maercker's "Introduction to Distillation," as revised by Drs. Delbrück and Lange, comprising raw material, malting, mashing and yeast preparation, fermentation, distillation, rectification and purification of alcohol, alcoholometry, the value and significance of a tax-free alcohol, methods of denaturing, its utilization for light, heat and power production, a statistical review, and the United States law. The present work is based upon the researches and writings of the most eminent of Germany's specialists in the science of fermentation and distillation. It covers the entire manufacture of alcohol from the raw materials to the final rectified and purified product. It also contains chapters on the methods of denaturing, domestic utilization of alcohol for heating and and lighting purposes, and alcohol as a fuel for power production. An illustrated circular and table of contents of this book will be sent on application.

NEW YORK, SATURDAY, MARCH 19th, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## A TRIUMPH OF MODERN STEAM ENGINEERING

AMONG the many brilliant successes of the steam turbine none surpasses the results which have been obtained at the Fifty-ninth Street power house, which operates the heavy service of the New York Subway. Here, by the introduction of a low-pressure turbine between the low-pressure cylinder exhaust and the condenser, not only has the output of the present reciprocating engine been doubled, but there has been made possible an increase of nearly 150 per cent in the economic capacity of the whole plant.

In a recent issue of the SCIENTIFIC AMERICAN we gave a preliminary statement of the truly remarkable work which is being done at this station. At that time one of the turbines was in place and the tests had not been carried to full completion. In the interim, more complete data have been secured, and at the last meeting of the American Society of Mechanical Engineers a paper was given by H. G. Stott, Superintendent of Motive Power of the Interborough Company, and R. S. Pigott, in which a very complete statement of the installation and its results was made public.

During 1908 it became apparent that the rapidly increasing traffic in the Subway would render it necessary to provide additional power for the winter of 1909-1910. The main power plant consisted of nine 7,500-kilowatt (maximum rating) compound Corliss engines and three 1,250-kilowatt turbine units for lighting and signal purposes. Of these engines and generator units the authors of the paper say: "In general they are the most satisfactory large units ever built, as five years' experience with them has proved."

In considering the problem of securing an additional supply of power, electric transmission of power from a hydraulic plant was rejected because of the high cost of a double transmission line from the nearest available water power and the impossibility of getting reliable service.

The gas engine, it will surprise many of our readers to learn, while offering the highest thermodynamic efficiency, would have cost at least 35 per cent more than an ordinary steam turbine plant, and its maintenance and operation account would have been from four to ten times greater.

The alternative of building more reciprocating engines of the type already installed was rejected (in spite of their most satisfactory performance) because of the high first cost and the small range of economical operation (between 3,500 and 8,500 kilowatts), the water rate rising very rapidly beyond these limits.

As between the installation of high-pressure and low-pressure turbines, it was found that by combining a low-pressure turbine with the present engine at least 8 per cent higher efficiency would be secured than with a high-pressure turbine unit alone, and it was finally decided to place an order for one 7,500-kilowatt (maximum rating) turbine unit, since by this means "the company would not only get an increase of 100 per cent in capacity of the combined engine and turbine," "but at the same time give the engines a new lease of life by bringing them up to a thermal efficiency higher than that obtained by any other type of steam plant."

The net results obtained with this first installation are summarized as follows: An increase of 100 per cent in maximum capacity of plant, an increase of 146 per cent in economical capacity of plant, a saving of approximately 85 per cent of the condensed steam for return to the boilers, an average improvement in economy of 13 per cent over the best high-pressure turbine results, an average improvement in economy of 25 per cent (between the limits of 7,000 kilowatts and 15,000 kilowatts) over the results obtained by the engine units alone, and lastly, an average unit thermal efficiency between the limits of 6,500 kilowatts and 15,500 kilowatts of 20.6 per cent.

These results are surely entitled to be considered as constituting the low-pressure turbine one of the greatest triumphs of modern steam engineering.

## AN AMERICAN GIBRALTAR

KEY WEST, by virtue of its geographical position, stands in the same strategic relation to the Gulf of Mexico and the Caribbean Sea as does Gibraltar to the Mediterranean, and its naval and military importance, which have always been recognized, have been greatly increased by the results of the late Spanish war and the construction by the United States government of the Panama Canal. The transformation of Key West into a great naval and military station which shall rival in importance the fortress of Gibraltar is advocated at considerable length in an article by Commodore W. H. Beehler, U. S. N., Commandant of the Seventh Naval District, which appears in the March number of the Journal of the Military Service Institution. The first part of the Commodore's paper is devoted to an urgent plea for the more complete co-operation of the army and navy forces. The army and navy should be as intimately connected as are the navy and the marine corps, and this connection should include, as far as possible, both the personnel and material. Guns and ammunition should be of the same general type, with the latter interchangeable, and supplies and stores should all be of one standard. It is admitted that close relations between the army and navy would be subject to certain limitations, but the Commodore urges that it *is* essential that the coast artillery corps and the navy should be intimately associated for the efficient defense of our seaboard. There should be a definitely assigned portion of the navy to act as Navy-Coast-Defenders, and in this class should be included second-class battleships or older battleships, the smaller torpedo boats, scouts, submarines, mine-laying vessels and tugs. "Their co-operation in the defense of any particular naval base should be definitely arranged in time of peace, and they should maneuver and drill *now*, under the command of a designated officer of the coast defense service, whether he be an army or a naval officer."

In his proposal to make of Key West an impregnable Gibraltar, it is pointed out that the present defenses at Fort Taylor are inadequate for the reason that battleships can lie at the entrance buoy seven miles south of Fort Taylor, beyond the range of the 12-inch rifle mortars, and destroy Key West from that point without being exposed to any danger, the remaining velocities of projectiles from the direct-firing 10-inch and 12-inch guns being insufficient to penetrate the armor of any battleship, whereas these same caliber guns on a battleship could shell the city of Key West and completely destroy it.

This consideration brings the Commodore to his novel proposal for rendering Key West impregnable. He points out that in place of high hills or a huge rock as at Gibraltar, for the mounting of coast defense guns, Key West Harbor, twenty-five miles in length, is sheltered on the north by a line of low reefs and shoals which form a complete protection on that side, while seven miles to the south of this line there is a parallel line of eastern shoals, some of which are scarcely awash at low tide and none more than eight feet above high water. To build forts on these outer reefs would be so costly that it could scarcely be considered, but Commodore Beehler proposes to take our monitors and older battleships which have passed their period of usefulness on the high seas, mount them in selected positions upon these reefs, and utilize them as permanent turret forts. Thus, for instance, selecting the shoal known as Rock Key, where there is a small natural harbor, he would lighten the old monitor "Amphitrite" by the removal of her propelling engines, haul her into the harbor, build around the vessel a dyke of piling, rock, and riprap, and then fill in the space between the inner face of the dyke and the ship with material hydraulically dredged and deposited. He estimates that the work would not cost more than $50,000, and he claims that the sea-coast defenses would thus be increased by a double-turreted fort containing four 10-inch breech-loading rifles and provided with admirable protection. The vitals of the fort, that is the ammunition rooms, turret turning gear, etc., would be protected not only by the armor of the ship but also by many feet of the imbedding earth and riprap. The deck of the monitor would be about eight feet above mean low water, and the riprap would be carried up the sloping face and over on board, leaving only the turrets and superstructure exposed.

The ship as thus imbedded would furnish, says the Commodore, a complete, modern double-turreted fort, with every necessary feature to operate the guns, and with quarters for the officers and men of the garrison, and moreover, the entire cost of the installation would be less than the cost of maintaining such a ship in the navy for one year. The monitors "Miantonomah," "Terror," and "Puritan" could be installed upon the adjacent reefs, and the range of the sixteen 10-inch and 12-inch guns of these forts would command a large part of the Straits of Florida, and especially that part which is used by westbound vessels entering the Gulf of Mexico which navigate close to the Florida reefs to avoid the strong current of the Gulf Stream. Incidentally, it may be mentioned that the dyke would be extended in each case to form a small harbor of refuge for torpedo boats and submarines. Referring to the proposed island fortifications for the defense of the entrances of the Chesapeake, it is suggested that it would be a great economy if one of our old battleships such as the "Oregon" were used as a central point about which the island could be built.

Now, it is a question of great interest and of unquestionable moment, whether this very novel proposal of the Commodore does not provide an opportunity to greatly lengthen the useful life of the battleship. In view of their enormous and rapidly growing first cost, the rapidity with which these instruments of war depreciate in military value is something appalling. In a few years after their completion they are unfit to lie in the first line of battle, in ten years' time they are becoming obsolete, and in fifteen years' time they must be relegated to the limited rôle of coast defense. The depreciation is not in the guns and armor but in the motive power, speed, and coal capacity. Many of these obsolescent ships, because of their powerful armor and armament, would be perfectly well able to stand up in the first fighting line, if they only possessed the requisite speed and maneuvering quality, and if it should be found practicable to utilize them in the way suggested by Commodore Beehler, their powerful guns and heavy protection would render them most formidable when mounted as part of the permanent fortifications of our sea-coast defenses. This suggestion is certain to excite a widespread interest, and we commend it for discussion in our columns by that large and ever-growing circle of our readers who follow closely the development of naval and military material.

## PAULHAN'S FLIGHT NEAR NEW YORK

AVIATOR LOUIS PAULHAN succeeded last week in getting the bond which he is required to put up in case he flies reduced to $6,000 for one week, and on Friday, March 11th, he made two exhibition flights at the race track near Jamaica, L. I., before some 300 invited guests. Wilbur Wright and his lawyers were interested spectators, as it was thought that M. Paulhan would attempt to fly with his vertical rudder tied or else without using the stabilizing flaps or ailerons. There was an 8 to 10-mile breeze blowing, and by starting against the wind Paulhan left the ground after a run of about 75 feet. He rose rapidly, and in the course of the two circuits of the track, made in 2:44, he reached a height of 75 to 100 feet. The biplane flew well and was not affected appreciably by the wind. Despite the sharp turns the machine did not tip very much in making them. It appeared to rock and pitch slightly, but was always under perfect control. The descent was made rapidly and at an angle of about 20 degrees. M. Paulhan made two more circuits in 2 minutes and 38 seconds.

## REQUIREMENTS FOR THE SCIENTIFIC AMERICAN TROPHY FOR 1910.

THE third annual competition for the handsome trophy given in 1907 to the Aero Club of America by the publishers of the SCIENTIFIC AMERICAN is now open to all aviators. As aviation has at last reached a stage where cross-country flights of a considerable distance are being made, it has been decided to award the trophy for 1910 to the aviator who makes the longest cross-country flight in excess of 50 miles, which has been fixed as the minimum distance. A round-trip flight of 25 miles each way will also fulfill the conditions. The flight may be made at any point in the United States that is convenient for the aviator, who must notify the Aero Club of America or the SCIENTIFIC AMERICAN a sufficient time in advance to allow of the sending of a representative of the club to officially observe it. The competition is international, and foreign aviators are invited to compete for the trophy whenever occasion allows.

The dates of the international balloon and aeroplane races for the Bennett trophies have been fixed by the Aero Club of America. The balloon race will be held at St. Louis on October 17th, and the aeroplane race above the Hempstead, L. I., plains (probably) on October 22nd. Plans are also on foot to hold big aviation meets at San Antonio, Texas, in April, at Atlantic City, N. J., in July, and at St. Louis in October.

## ENGINEERING.

**The United States** army has recently adopted a new type of machine gun which can be carried by one man, while two such guns with a full equipment of stands and ammunition can be packed upon a mule. The new weapon can be fired from the shoulder. The barrels are carried in duplicate, and can be rapidly changed when they become heated from continuous firing.

**In a recent** communication to Flight on the relative military value of aeroplanes and airships, Col. Capper of the British army believes that the improved aeroplane will have the dirigible at its mercy. He predicts that the future aeroplane will be able to ascend to heights of 10,000 feet and over, from which it will swoop down and destroy the more slowly moving dirigibles below.

**The New Haven Railroad** has proposed to the city of Boston to enter into the joint construction of a tunnel between the North and South stations in that city. They offer to spend $16,000,000 on the construction of the tunnel which is to be electrically operated, provided the city will bear the expense of $10,000,000, which it is estimated will be the cost of the purchase of the necessary land.

**One of the most remarkable features** of the New York Public Library, now slowly nearing completion, will be the huge stack room, 90 feet wide, 300 feet long and 60 feet in height, containing seven tiers of stacks. The metal work of the stacks alone weighs about 3,000 tons, and recently, in estimating for the painting contract, it was found that merely to pass once through the multitudinous nests of stacks it would be necessary to cover seven miles of distance.

**The last** annual report on the shooting in the British navy shows that the percentage of hits to rounds fired during 1909 was 64.67. In 1905 it was 20.02, in 1906, 74.60, in 1907 35.81, and in 1908, 58.42. The significance of these figures will be evident when it is stated that in 1907 the size of the target was greatly reduced, the number of hits in that year being consequently only slightly greater than in the year preceding.

**The placing** of a large order by the Admiralty for liquid fuel has led to exaggerated statements in the London Express to the effect that the British navy contemplates the practically exclusive use of oil fuel. There is no truth whatever in this statement. A few hundred tons of oil will be carried in future battleships as an auxiliary to coal, and oil will continue to be used as fuel in certain classes of torpedo boats. Great Britain possesses no such extensive oil fields as would warrant a drastic change of this character.

**A general scheme** for constructing a north breakwater to the entrance of the Panama Canal has been approved, and the preparatory work is being done. The breakwater will protect shipping in the harbor at Colon, and will shelter vessels which are making the north entrance to the canal from the violent 'northers' which prevail from October to January. There will be two jetties of rock, which will extend from Toro and Manzanillo points until they reach depths of water of 48 and 44 feet, respectively.

**Some injudicious** statements were made recently by Representative Rainey about the new 14 inch coast defense gun, which is undergoing test at Sandy Hook, in the course of which he spoke of the gun as having 'burst' on trial. As a matter of fact, the gun has shown excellent results, and given much satisfaction to the army men. The accident, which was a trivial one, consisted in the breaking of a part of the mechanism of the disappearing carriage, which delayed the tests only a few days, and was quickly made good.

**It is** now officially stated by the Pennsylvania Railroad Company that the four tubes under the East River and the electric service as far as Jamaica will be placed in operation on May 15th. The trains will run, under a five-minute headway, from the new terminal at Thirty-third Street to Jamaica without a stop, in 18 minutes. The main yard, station, and offices on Long Island will be built at Jamaica, where $3,000,000 will be expended for this purpose. The tunnels to New Jersey will be in operation by July 1st, and the lines along the north shore to Great Neck early in January, 1911.

**In London Engineering** Mr. A. A. C. Swinton describes a model steam-propelled aeroplane built by C. A. Parsons of turbine fame, which made successful flights in 1893, thus antedating the Langley aerodrome by three years. The boiler, 2½ inches in diameter, supplied steam to a cylinder 1¼ by 2 inches, the total weight of engine, propeller, and water being 1¼ pounds. The aeroplane consisted of two wings and a tail built of a silk-covered, cane framework, the whole apparatus with engine weighing 3½ pounds. The model made several flights of about 100 yards distance, coming down when the steam pressure was exhausted. The boiler, which carried 50 pounds, was heated by a spirit lamp.

## ELECTRICITY

**In an article** in La Revue Electrique, on the effect of high temperature on insulating materials used in dynamo-electric machinery, it was pointed out that cotton does not show any injury when exposed to temperatures below 105 deg. C., but that at 115 deg. C. it begins to deteriorate and above 125 degrees it rapidly disintegrates.

**The reputation** for efficiency of the New York telephone service has spread all over the world. In Paris the service has been so poor of late that the subscribers have organized to demand improvements. Quite recently the Ministère des Postes et des Télégraphes of France applied to the vice-president of the New York Telephone Company, asking if he would be willing to train six telephone officials from Paris in the various methods employed in New York. The request was gladly acceded to.

**An office** was recently opened in Chicago by the Telepost Company which employs the Delany rapid telegraph system. As described some years ago in the Scientific American, a perforated paper tape is used, by which the signals are transmitted over the line at high speed. To avoid the overlapping of successive signals because of the line capacity, each signal is made up of a positive impulse followed by a negative impulse. At the receiving station the message is recorded on a chemically prepared tape.

**A recent** number of the Electric Railway Journal describes briefly a peculiar electric locomotive used for canal haulage near Bremen. The locomotive runs on a quay, which has to be kept clear for the passage of drays. In order to secure the requisite weight for adhesion, the locomotive is built in the form of two inverted U's connected at the top with a girder. The width of each base is only 28 inches and so the driving motor had to be placed in the upper part of the structure. The locomotive thus straddles the traffic and can travel up and down the quay without disturbing the trucks, which pass between the U's and under the connecting girder.

**A special type** of motor has been built for a British powder factory in which precautions have been taken to render the motor flame proof and explosion proof. The motor case is very strongly built, so that it will stand explosion of dust or gases which might find their way into it. The joints of the motor case are packed with hemp rope dipped in tar, this being considered more durable than rubber at high temperatures. The bearings are also specially packed to prevent the escape of hot gas in case of explosion within the motor. No ventilation for the interior of the motor is provided, but the casing is formed with corrugations which furnish a large cooling surface.

**In the discussion** which followed the reading of a paper on underground conduit construction for large transmission systems before the American Institute of Electrical Engineers in Chicago the following illustration was given to point out the advantages of concrete over tile because of its lower thermal conductivity and its better heat resistance. A burn-out occurred in a 1,000,000 circular mil 230-volt cable in the middle of a 9-duct outlet from a manhole. On examination it was found that the conductor had been completely consumed, but the concrete was burned to only a quarter of an inch while the cables in the ducts above and below showed not the slightest injury. Had tile been used instead of concrete, the heat developed would have been sufficient to damage the conduit very seriously.

**The naval gun factory** at Washington, D. C. is equipped with six cranes four 40-ton cranes on the first track, a 110-ton crane on the next track above and a 200-ton crane on the third track which is 160 feet above the ground floor. The track is 600 feet long running the full length of the gun factory. The shrink pit is located at one end of the shop making it a difficult matter to call a certain crane. Accordingly an annunciator system has been installed on each crane with a push button for each crane located on a board close to the pit. These buttons are connected to the annunciator in the crane cab by light trolley wires strung along the web of the I beam that supports the cranes. In this way either crane can be called by pushing the button. If the crane is busy the call will show on the annunciator.

**The very first** day of the inauguration of letter telegrams proved the success of this method of communication and gave promise of a great future. The principal business was done between the large commercial centers, such as New York, Boston, Chicago, St. Louis and New Orleans. By this system a 50-word message may be sent at night at the price of the ordinary 10-word message. At the receiving end the message is deposited in the nearest post office for delivery by the first morning mail. Thus the wires are kept as busy at night as in the daytime. A great deal can be said in fifty words, so that quite a lengthy message can now be sent to distant points in less time and cost than formerly.

## SCIENCE.

**On March** 6th Vesuvius suddenly became active again. There was a continuous eruption for twenty four hours of red hot stones and ashes, accompanied by internal detonations. Several fissures opened, from which gas and lava emerged in great quantities.

**Prof. Wilhelm Trabert** has been appointed director of the Central Institute for Meteorology and Geodynamics at Vienna, succeeding the late Prof. Josef Maria Pernter. As director of this institution he is the official head of meteorology in Austria.

**Dr. Felix Exner** of Vienna has completed the great treatise on meteorological optics begun by the late Prof. J. M. Pernter in 1902, about two-thirds of which had been published up to the time of Pernter's death in 1908. It is the only extensive modern work on this subject.

**The commission** appointed to examine the Leaning Tower of Pisa has reported that it thinks its foundations may need strengthening. A spring exists under the tower, the water of which is raised by steam pumps for the use of a local factory. As the bed of the spring is emptied, it is feared, a subsidence of the ground on which the campanile stands will follow.

**Dr. Herman C. Bumpus**, director of the American Museum of Natural History announces that up to last August, at least, V. Steffansson and R. M. Anderson, the museum's Arctic explorers were safe. A letter from Mr. Steffansson, from Herschel Island in the Arctic Ocean dated August 19th, 1909 has been received telling of the adventures and successes of the party.

**The task** which the American south polar expedition had set itself to perform in the opinion of Sir Ernest Shackleton was much harder than was generally recognized inasmuch as no one had ever landed in the place where the exploring party purposed to land. Indeed no one had ever seen land there although there was an ice cliff 150 feet high which was called land. Still, Americans might find land in that locality.

**Dr. Le Faguays** recommends a process of disinfection which consists in blowing upon the contaminated surfaces a current of air heated to a very high temperature (600 to 900 deg. F.). This process may be applied not only within buildings, but also to the surface of streets, yards, etc. The apparatus is heated by petroleum and is very simple. This process not only destroys disease germs but it is very efficacious against fleas and other vermin.

**Kuhne** has devised a process for the manufacture of sulphuric acid based upon the employment of the ultra-violet rays emitted by mercury vapor lamps. A mixture of air and sulphurous acid gas is introduced into a tower, lined with lead, into which water is injected in fine jets. Under the influence of the ultra-violet radiation of lamps in the tower, the sulphurous acid is entirely converted into sulphuric acid. Several towers are connected together. The strength of the sulphuric acid solution obtained in the first tower can be increased by spraying it instead of water, into the second tower. In like manner, the product of the second tower is sprayed into the third, and so on. In the last tower however pure water is again used as soon as any sulphurous acid appears in the escaping gases.

**The Zeppelin** North Polar Exploration Committee met recently under the Presidency of Prince Henry of Prussia. Count Zeppelin, Prof. Hergesell and Prof. Lewald were among those present. The committee discussed the programme for the summer's work which will be devoted to a preliminary expedition for the purpose of studying ice conditions. The government will be asked for the use of the exploring vessel "Poseidon" for about two months. The expedition will start for Spitzbergen July 1st on an excursion steamer, and there will transfer to the Poseidon. A Norwegian ice steamer will be used for the purpose of forcing an entrance into the polar ice and the expedition will return at the end of August. Apparently no airship will be taken for summer use.

**For once** the bacteriologists and hygienists, who usually appear to delight in alarming timid folk, announce a discovery which will reassure those persons who are afraid to eat green vegetables. Manau thought that he had discovered soil microbes in the interior of vegetable stalks. From this discovery resulted the condemnation of sewage farms and, indeed, of all market gardening as it is ordinarily practised, with the employment of manure. Fortunately this opinion has not been shared by all bacteriologists. In order to solve this problem which is so important from the hygienic point of view, Remlinger and Nouri have undertaken a series of experiments, in which they endeavored, by every possible means, to infect plants with microbes. In every case however, they found it impossible to obtain colonies of microbes from the interior parts of the plants thus infected. Hence they conclude that the microbes in the soil do not penetrate into the interior of plants, but remain entirely upon the surface.

## NEW AEROPLANES AT HOME AND ABROAD

### THE "BADDECK NO. 2" AEROPLANE.

A noteworthy aeroplane so far as actual flying is concerned is the "Baddeck No 2" of Messrs McCurdy and Baldwin, who are still working with Dr Bell near Baddeck, Nova Scotia. As our photographs show, this biplane is an excellent flyer It has made a considerable number of more or less lengthy flights above the ice of Lake Bras d'Or, in a number of which passengers were taken

The planes of the McCurdy and Baldwin machine are 40 feet long by 7 feet wide at the middle, decreasing to 5 feet at the ends The wing tips which are double and attached at each end of the main planes, are about 5 by 5 feet in size They are hinged near their front edges, and rocked in the usual manner by means of a fork fitting around the aviator's shoulders The horizontal rudder consists of two superposed surfaces spaced 30 inches apart, and mounted 15 feet in front of the front edge of the main surfaces The surfaces of this rudder are 12 feet by 28 inches in size A biplane tail is also used, the planes being the same size as those which form the front rudder This tail is mounted 11 feet from the rear edge of the main planes. The horizontal and vertical rudders are operated by a wheel in the same way as on the Curtiss biplane In other words, a push forward or a pull backward on the wheel directs the machine downward or upward Turning the wheel to the right or left steers the machine sideways.

The motive power of this biplane is a 6-cylinder Kirkham automobile motor of 40 horse-power It is water cooled and develops its rated power at 1,400 R.P.M., at 2,000 R.P.M. it develops 48 horse-power The radiator is novel, consisting of thirty flattened tubes 7¼ feet long by 3 inches wide by 3/32 inch thick These tubes are curved from front to rear in the same manner as the main planes, and sufficient lift is obtained to support the weight of the radiator and water carried The motor is geared to a single 7 foot 8-inch propeller having a 6 foot pitch, by means of a chain, the ratio being 3 to 5 The thrust obtained is sufficient to drive the machine at a speed of over 40 miles an hour

**The Herring Biplane, showing novel stabilizing fins.**

This new biplane has several new features, such as foot operation of the horizontal rudder, fins for automatic transverse stability, a skid instead of wheels, etc.

The chief features of Messrs McCurdy and Baldwin's biplane are the use of a comparatively heavy 6-cylinder automobile motor and the fitting to the machine of a biplane tail of the same shape and size as the horizontal rudder The 6-cylinder motor has been found superior to the 4-cylinder for automobile work, but this is the first aeroplane, so far as we know, to be fitted with this type of motor The motor is placed low down upon the lower plane in order to keep the center of gravity low while the propeller is mounted higher up, so that the center of thrust shall be as near as possible to the center of resistance of the aeroplane. The usual three-wheel chassis, first used by the Aerial Experiment Association, of which Messrs. McCurdy and Baldwin were members, is fitted to the machine.

After making numerous satisfactory flights above the frozen surface of the lake, Messrs. Baldwin and McCurdy were visited on the 9th instant by Major Munsell of Ottawa, who represented the military department of Canada. The two inventors made five exhibition flights for this officer, and finally he consented to make a flight as passenger with Mr McCurdy A very satisfactory flight of several minutes' duration was made. Messrs. McCurdy and Baldwin made a number of flights last summer and fall in Canada, and the Canadian government is very much interested in their machine, and will doubtless eventually purchase one for military use The noteworthy point about this machine is that its makers have built it sufficiently large to carry a weighty and reliable motor, and there is little doubt that the machine is capable of making extended flights without difficulty

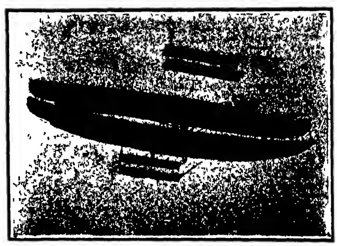
### THE NEW HERRING BIPLANE.

The best constructed aeroplane on exhibition at the Boston show, as noted in previous issues of this journal, was the new biplane of A. M Herring The photograph of this machine, reproduced above, was taken at the time of the trial flight on March 1st, and it gives a very good idea of the biplane's novel features. The spread of the planes is about 28 feet, and the fore-and-aft width about 4 feet, the total supporting surface being 220 square feet. A 25-horse-power Curtiss motor is mounted upon the lower plane at the rear, and carries upon its crankshaft a 4 bladed 6-foot propeller of 5-foot pitch, designed by Mr Herring. The total

*(Continued on page 246.)*

**Capt. Baldwin's novel biplane.**

The rudder above the upper plane is worked by a fork fitting about the aviator's shoulders. It corrects the side-tipping of the aeroplane.



**Messrs. McCurdy and Baldwin flying in their "Baddeck No. 2" biplane.**

This is the first aeroplane to be equipped with a six-cylinder automobile motor It has made many successful flights in Canada.

**Sir Hiram Maxim standing behind his new biplane.**

This machine is similar in many respects to the inventor's gigantic aeroplane built nearly 20 years ago.

**Rear view of Bleriot XI. bis monoplane, showing the new tail.**

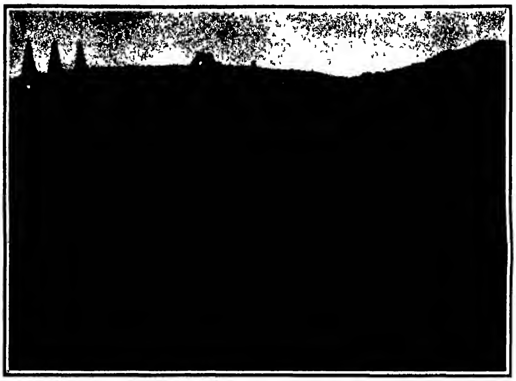
Note the complete covering of the body, and the large horizontal rudder at the rear end of the tail.

NEW AEROPLANES AT HOME AND ABROAD.

**BUILDING THE OLIVE BRIDGE DAM FOR THE CATSKILL WATER SUPPLY.**

Work on the Catskill water supply, which will provide New York with five hundred million gallons of water daily, is making steady progress, as will be evident from the illustrations of this work which are herewith presented. Briefly stated, the schema consists of the construction of a large reservoir in the Esopus watershed in the Catskills, with a storage capacity of 127 billion gallons and an aqueduct 92½ miles in length for conveying the water to the New York city line. The Ashokan reservoir, as it is called, will supply the city with 250 million gallons daily in addition to the 375 million gallons now available in the reservoirs of the Croton watershed. As the future needs of the city demand it, reservoirs will be built in the Rondout and Schoharie watersheds adjoining the Esopus Valley and from these three dams it will be possible to draw sufficient water for the full capacity of 500 million gallons daily of the new aqueduct. The latter passes through the Croton watershed and in two years time, and before the full completion of the Ashokan reservoir, a portion of the water stored therein will be available for delivery through the new aqueduct to the new Croton dam. The work is to be completed by February, 1915.

The Olive Bridge dam which will create the Ashokan reservoir, is a huge structure with a maximum height from the lowest foundation of 240 feet and a width along the crest of 4 830 feet. The central portion immediately above the river is built of cyclopean masonry and extends for 1 000



Present condition of Olive Bridge dam as viewed from north bank.

A completed section of the 92½-mile steel-and-concrete aqueduct

Site of dam, showing the 8-foot pipes for passing river through the work.

Placing steel reinforcement for the concrete aqueduct.

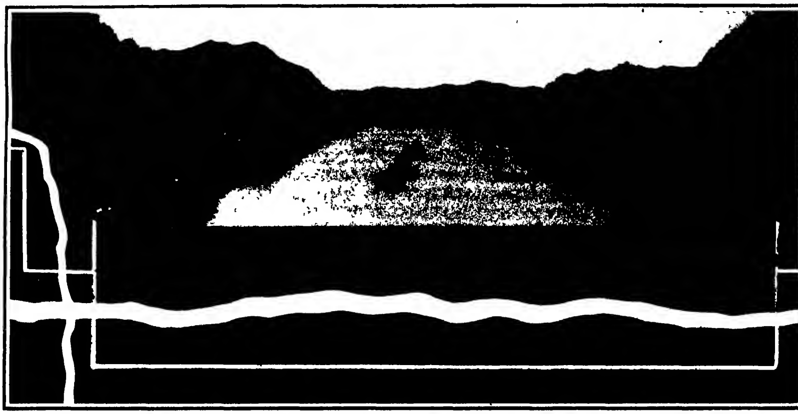
BUILDING THE OLIVE BRIDGE DAM FOR THE CATSKILL WATER SUPPLY.

feet in width The rest of the dam consists of a central masonry core wall and carefully laid and rolled earth In addition to the main dam there are two series of embankments known as the Beaver Kill and Hurley dikes the former extending for 11 144 feet and the latter for 2 200 feet In addition to these works there is a waste weir 1 100 feet in length and a dividing dike and weir 2 200 feet long Taken altogether the masonry and earthworks necessary to close the valley depressions and raise the water to the desired height measure five and one half miles in aggregate length

had been reached, a large culvert, 35 feet wide by 40 feet high, of sufficient size to take care of any possible floods coming down the valley, was formed in the wall of the dam As soon as the vertical walls had been carried up a sufficient height to accommodate the river, the latter was diverted through the culvert and the 8-foot pipes were removed Some interesting work was done in building the roof of the tunnel, a series of framed steel brackets or cantilevers being placed on each side of the opening, from which the wooden forms for the arch of the tunnel were suspended Then as the masonry was laid, a series of

above mean sea level. Its thickness will be 28 feet at the crest, its maximum thickness at the base about 200 feet, and the masonry work will contain 550,000 cubic yards of material. The maximum width of the earth-and-core-wall wings of the dam will be about 800 feet, their top width, about 34 feet, and the total quantity of embankment will be about 2,000,000 cubic yards. The elevation of the discharge will be 590 feet above tide level.

The Beaver Kill dikes, which have a total length of about 2.8 miles, will have a maximum height of about 110 feet above the original surface, and they will con-



Cross-section of the Hudson River near Cornwall, showing how the Catskill water supply will be carried under the river in a pressure tunnel in the solid rock 1,200 feet below tide level

The accompanying photographs, for which we are indebted to the MacArthur Brothers Company, who have contracted to build the main dams of the Ashokan reservoir for over twelve and a half million dollars serve to illustrate the character of the work The earliest of the operations consisted in providing a bypass in the form of two 8 foot steel pipes for carrying the flow of the Esopus Creek past the dam during the work of excavation, and the construction of the masonry up to the level of the river When this level

heavy steel I beams were placed transversely to the axis of the tunnel from which the forms with their super incumbent load of masonry were suspended by vertical tie-rods To facilitate the flow of the water, the wooden forms will be left in place until the dam is completed Then the flow will be diverted, and the tunnel will be filled in with masonry When this is completed, the filling of the reservoir will take place

The top of the Olive Bridge dam will be 610 feet

tain about 5 000,000 cubic yards Like the earthen portions of the Olive Bridge dam, they will be built with a concrete core wall The reservoir will be divided by a dike into two basins This dike will have a length of 1 100 feet, and the dividing weir will have the same length

It will be readily seen from these figures that the Ashokan works are on an immense scale They involve over 2,000,000 cubic yards of earth and 425,000

*(Continued on page 249.)*

**BUILDING THE OLIVE BRIDGE DAM FOR THE CATSKILL WATER SUPPLY.**

**An Important German Patent Decision.**

A very important case was recently decided by the Supreme Court of the German Empire, First Civil Senate, in which the rights of American patentees in Germany are defined The facts in the case are briefly these

The National Cash Register Company of Berlin, a limited liability company incorporated under the German law, is the owner of three German patents. In Germany the patentee must work an invention within three years from the date of publication That term had expired for all four patents Proceedings were instituted by Schubert & Salzer Machine Works in the Imperial Patent Office to revoke these patents on the ground that they had not been worked to an adequate extent in Germany, and that in all their essential parts the cash registers protected by the patents were manufactured by the National Cash Register Company of Dayton, Ohio, and were imported from the United States into Germany In its defense the National Cash Register Company of Berlin stated that one German patent had been worked in Berlin, and that this patent was in substantial agreement with the American patent covering the identical points of invention, that the other three patents were not worked in the German Empire, but that their revocation would not serve any public interest The Imperial Patent Office revoked all four patents, arguing that the one patent which was worked in Germany was not identical with the American patent cited by the defendant

The National Cash Register Company appealed from the decision of the German Patent Office on the ground that the German Patent Office erred in holding that the German patent alleged to be identical with the American patent was not worked in Germany, and still setting up the old defense that the revocation of the remaining three patents would not further public interest Pending the appeal the National Cash Register Company of Berlin changed its firm name so that it read National Registrierkassen-Gesellschaft mit beschraenkter Haftung All four patents were assigned by this now company to the National Cash Register Company of Dayton, Ohio, so that the patents no longer belonged to a German but to an American firm Pending the appeal, one patent became void for failure to pay the annual tax, and another patent was abandoned There remained for consideration the validity of the German patent which was worked and which was alleged to be identical with the American patent, and another German patent which was not worked The National Cash Register Company of Dayton, Ohio, on petition was permitted to interplead as a party to the suit in place of the German company because it was the assigner of the patent rights

The first question which came up before the court was whether the American company could be permitted to act as the defendant on appeal in view of the fact that the German company had been the defendant when the action was brought before the German Patent Office The point depended upon an interpretation of Section 265 of the German Civil Code The Supreme Court decided that it was not a violation of that section of the Civil Code to substitute the American company for the German company as defendant The forfeiture of the patents involved a consideration of the treaty of February 23rd 1909 between the German Empire and the United States of America relating to the mutual protection of industrial property That treaty became a German law on August 1st, 1909, and affected the patents which had been assigned to the American company The treaty provided in substance that the American patents of Germans and the German patents of Americans were to be restricted in their respective countries only so far as they were restricted by the opposite contracting party's laws The German patent law compels the working of patents in the German Empire on pain of forfeiture within three years. On the other hand, there is no law in the United States to compel the working of patents The court therefore holds that the treaty exempts American citizens from the obligation of working their German patents in Germany because German citizens are not compelled to work their American patents in the United States Hence, because the patents for which forfeiture was demanded were the property of an American company, the decision of the German Patent Office was reversed.

As a result of this very important decision, an American citizen stands in a better position before the German courts, so far as forfeiture is concerned, than a German subject. It is usually the object of a treaty to secure equal rights to the contracting parties, but in this case it would seem that a very liberal interpretation of the treaty gives to American citizens probably more than they originally bargained for

**The Current Supplement.**

The opening article of the current SUPPLEMENT, No 1785, is by L. A. Bauer, Director of the Department of Research in Terrestrial Magnetism, in which he describes the instruments and methods of the ocean magnetic work of the Carnegie Institution of Washington The article is elaborately illustrated. Extracts from affidavits submitted in the case of Wright vs Paulhan, as well as Judge Hand's decision, are given In this decision the Farman, Blériot, and Wright machines are considered from the patent lawyer's standpoint The Berlin correspondent of the SCIENTIFIC AMERICAN writes a fascinating article on the number of particles projected by cathodes It seems almost incredible that invisible particles smaller even than atoms can be counted, and yet in this article the method of so doing is described Prof K Svehla points out the disinfecting qualities of a sad iron The powerful passenger and freight locomotives of the Mallet type recently built for the Atchison Topeka and Santa Fe Railway are described W P Dreaper's article on the artificial silk industry is continued P H Cowell writes on Halley's comet as seen from the earth He gives a table of ecliptic coordinates in two decimal places at intervals of four days through an arc extending from one end to the other of the *latus rectum* of its orbit, as well as a diagram giving the position of the earth for six days in May, also the position of the comet on twenty seven days measured from perihelion passage in days Some novel toys are described and illustrated

**A German Antarctic Expedition.**

A German south polar expedition has been virtually arranged by Lieut Filchner of the General Staff, under the auspices of the Geographical Society Lieut Filchner announced at a meeting of the society that the expedition would start in October of this year if the necessary funds were forthcoming

The plan is to send a vessel with provisions over the route followed by Lieut Shackleton and form a depot at about the half way point to Shackleton's winter headquarters The regular expedition would start later from Weddell Land on the opposite side of the pole and make a dash across with the depot as objective

Dr Penck, chairman of the Geographical Society announced that an anonymous donor had given $75,000 toward defraying the cost of the expedition, and Lieut. Filchner had promises of a further $15 000 It was hoped, he said, that they would be able to send out two vessels in order to save time

Lieut Filchner is an explorer of experience He was one of the first to reach Lhassa, Tibet, and in 1903 and 1905 he explored Turkestan and Persia

**The Life of Radium.**

An interesting and informative popular lecture upon the wonders of radium was recently delivered before the members of the Authors' Club in London by Sir William Ramsay, K C B In describing the wonders of this element the eminent chemist confined himself mainly to a description of his own investigations and experiments In dealing with the Alpha particles he explained that these were really gas, and quite two-thirds of the energy of radium was transferred to the gas which it emitted, which comes off at a regular rate, and this he pointed out raised the question as to how long radium would last He replied for over, as the amount of gas was always proportionate to the amount of radium present He likened this emission of gas to taking a slice of bread and cutting it in two which operation say occupied a minute, and then cutting one-half in two again, and so on continually cutting in two each successive half obtained How long would it take him to cut the bread entirely up? He could never do it. He would always be halving to infinity and the task would take him an eternity to perform. It was exactly the same with radium The amount of gas was always proportionate to the mass of radium existing and was always being produced There was however, he remarked, one point easily defined When would radium be half gone? They had just measured it in his (Sir William's) laboratory and had found that it would take 1,750 years so that anyone who invested in radium would retain at least one-half of the capital at the end of 1,750 years The Austrian government some time ago intrusted him with about half a gramme or one fifty fifth part of an ounce of radium for his private use Its value was about $45,000 Less than a year ago Dr Gray and himself performed the experiment of isolating the Alpha emanation of radium, and they inclosed it in a fine glass tube, much finer than the finest thermometer tube that was ever made They compressed it and liquefied it. In the latter stage it shone with a purplish light, although it was quite transparent like water When reduced to a temperature of —60 deg Cent it solidified and then it shone with an extremely brilliant light like a miniature electric arc light. The quantity they used was extremely small, being less than the point of the finest needle, yet they ascertained its boiling point, its melting point, and its specific gravity

Radium was the most concentrated form of energy known It is a substance which goes on changing into other things to which various names have been given These substances were named radium A, radium B, radium C and so on up to radium F Some had a very brief existence lasting only thirty or forty minutes, and he had never seen them He had seen radium D which would be gone in about forty years. This was a substance rather dull looking like lead and that was nearly all he could say about it There were other substances probably like polonium which Madame Curie discovered During these emanations radium gave a great deal of energy generally manifested as light but as a matter of fact radium kept itself hot, there was a great deal of heat generated It could be calculated, and it was found that it gave off about 3,500,000 times as much heat as would be given off by the oxyhydrogen blowpipe, which gave a temperature of over 2 000 deg Cent.

What did this energy do? It sent out the Alpha rays at a velocity of about 40 000 miles per second, and these particles naturally carried a great deal of energy The Beta rays, although only about one thousandth part of the size also carried tremendous energy owing to their enormous velocity, which exceeded that of the Alpha rays They could decompose water and metallic substances, and in these decompositions they found elements produced which they did not imagine to exist in the substances so treated For instance in decomposing ordinary copper sulphate they were surprised to discover lithium in what remained, and no traces of the copper salt He had repeated this experiment five times, and the experiments were still going on

Astronomische Nachrichten, No 4370 A C D Crommelin

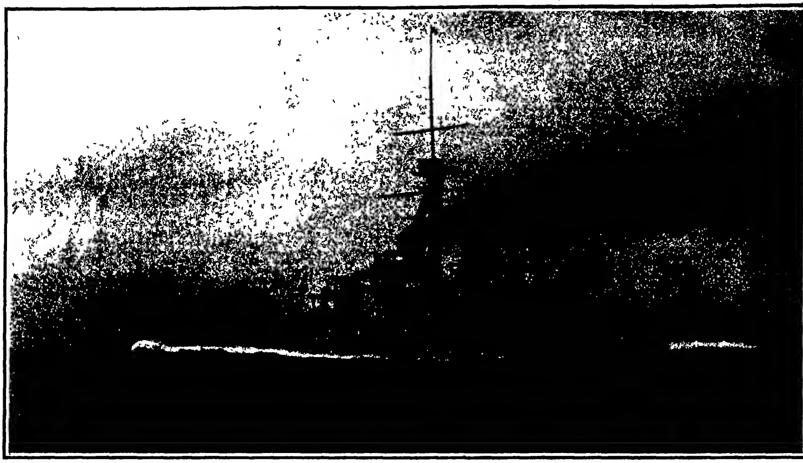
***Prizes for Small Aeroplanes.***

The practical utilization of the aeroplane is the object toward which the efforts of all constructors and experimenters are directed In furtherance of the same object, the French National Aerial League offers two prizes for small and easily managed aeroplanes One prize, offered by M René Arnoux through the agency of the League, will be awarded to the first aviator who shall succeed in starting from a selected road, bordered with trees and in landing on the same road after making a continuous flight of one kilometer (⅝ mile) or more The other prize, of 1,000 francs (about $200) will be awarded to the owner of the smallest aeroplane which shall make a continuous circuit of one kilometer The size of the aeroplane will be estimated by multiplying together the three maximum dimensions of the machine The competition will close July 16th 1910 A complete copy of the rules governing the competition can be obtained by addressing La Ligue Nationale Aérienne 27 Rue de Rome, Paris

The number of bacteria contained in milk increases very rapidly from the moment of milking for a certain time, and then slowly decreases Some bacteriologists have attributed this phenomenon to a bactericidal power possessed by the milk due to some unidentified ingredient Experiments have been made to isolate this hypothetical substance which appears to remain active up to a temperature of 140 deg F The milk was filtered through a porcelain cylinder, and the filtrate obtained showed greater germicidal power than ordinary milk, but no conclusive results were obtained The real explanation of the germicidal power of milk is much simpler The acidity of milk continually increases with age and thus milk continually becomes a less favorable medium for the growth of bacteria The bacteria also have to contend with the lactic ferments which develop very rapidly in sour milk and are generally victorious in the struggle for existence It is for this reason that the lactic ferments are employed in therapeutics

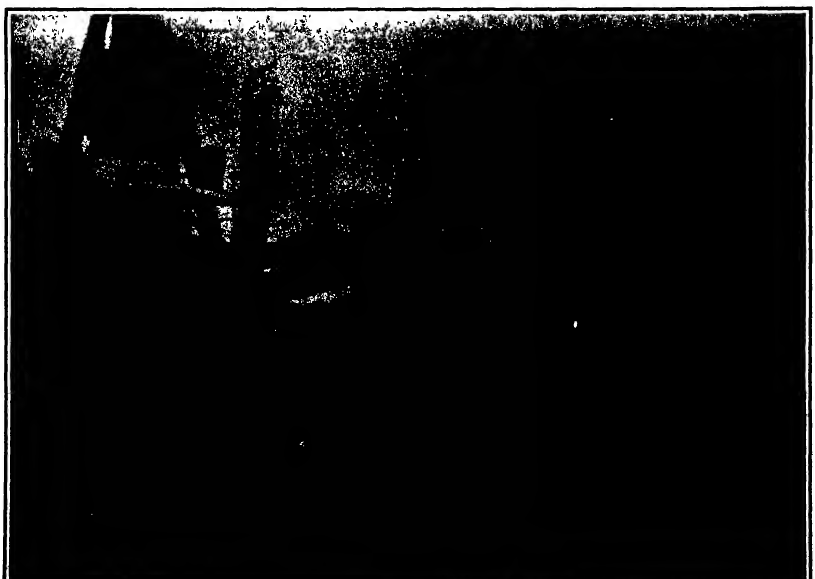
THE BRAZILIAN BATTLESHIP "MINAS GERAES"

In the early part of this year the first of the dreadnought battleships the "Minas Geraes" about which much speculation has been rife, was handed over by the builders, Sir W. G. Armstrong, Whitworth & Co. of Elswick, Newcastle-on-Tyne, to the Brazilian government thus definitely disposing of the supposition that the vessel was designed for some other power. This vessel has been the source of considerable discussion, since it represents the last word in heavy battleship design, and is at present the most powerfully armed warship afloat. Through the courtesy of Admiral Maurity, the president of the Brazilian naval commission in England, appointed by the government of the South American state to supervise construction,



**Length,** 543 feet. **Breadth,** 83 feet. **Normal displacement,** light, 19,000 tons. **Horse-power,** 27,212. **Speed,** 21.4 knots. **Armor:** Belt, 9-inch, extending for full height of hull; turrets, 9-inch; two protective decks, 1½ inch and 2 inch. **Armament:** Twelve 45-caliber 12-inch; twenty two 4.7 inch. Four torpedo tubes.

THE BRAZILIAN DREADNOUGHT "MINAS GERAES."



During the gun trials of the "Minas Geraes" ten 12-inch guns were trained on the broadside and discharged simultaneously. The combined energy of the projectiles amounted to 500,000 foot-tons, or sufficient to lift the ship bodily 26 feet into the air.

THE GREATEST BROADSIDE EVER FIRED FROM A BATTLESHIP.

we are enabled to publish the accompanying photographs and to give the leading particulars regarding this, the latest dreadnought.

The general appearance of the vessel may be gathered from the accompanying illustration The overall length is 543 feet, molded breadth 83 feet, molded depth 42.25 feet, displacement 19,000 tons, speed 21 knots. The propelling machinery, built by Vickers Sons & Maxim, who have the second vessel of the series completing at Barrow, is of the reciprocating four-cylinder triple-expansion type, driving twin three-bladed propellers. The cylinders have a diameter of 39 inches for the high-pressure, 63 inches for the intermediate, and 73 inches for the low-pressure, with a common stroke of 42 inches, and on the forced draft trial at 250 pounds pressure developed 27,212 indicated horse-power, giving a speed of 21 4 knots.

The outstanding feature of the vessel, however, is the armament. The main armor on the broadside amidships is 9 inches for a depth of 22 3 feet, 5 feet of which extends below the normal load water line. The forward and aft barbettes are protected by a transverse 9-inch armor bulkhead, while forward and aft the hull is protected by 6-inch belt armoring tapering to 4 inches at the extreme ends There are two protective decks, the upper being 1.25 inches thick, and the water-line deck 2 inches thick Nine-inch armor is also used for the upper strake amidships, and the 4 7 inch guns of the secondary armament are mounted within the citadel thus formed In regard to offensive armament, the main battery comprises twelve 12-inch 45-caliber guns Four are carried in pairs in two turrets in the center line of the ship, both forward and aft, the remaining two pairs being mounted on either side amidships. In order to permit these to be trained throughout a full arc of 180 degrees, the super structure is cut away fore and aft. It will be readily seen that the upper deck of the vessel is left clear of all obstruction, a factor which is one of the outstanding features of the design It will be seen also that the pairs of guns forward, as well as those aft, are stepped, the uppermost pair being some 12 feet above the level of those below, so as to enable the upper to fire over the lower pair It will be seen from this arrangement that a terrific gun fire can be concentrated on either side, for the forward and aft two pairs of guns can be trained through an arc of 150 degrees on either side of the center line of the ship, thus giving a fire from either broadside, including the pair of guns amidships of ten 12-inch guns Moreover, owing to a pair of guns fore and aft being set at a higher elevation, they have a corresponding advantage in action As these guns fire a projectile weighing 850 pounds, this means that an aggregate discharge of 8,500 pounds can be concentrated from either broadside In the accompanying photograph taken during the gun trials a full broadside fire is shown, and this is interesting as it is the first occasion on which ten 12-inch guns have been fired from a broadside. Similarly owing to the amidship guns on either broadside being capable of training through an arc of 180 degrees, it is possible to fire eight 12-inch guns ahead or astern.

The secondary armament comprises 4 7-inch guns and 3 pounders of the quick-firing type. The central superstructure of the vessel has been so designed as to carry four 4.7-inch weapons arranged in pairs one above the other on either side of the bridge at the forward end, with a similar disposition aft. These guns fire forward and aft parallel with the center line of the ship, but have a considerable angle of fire abaft the beam. Also six 3-pounders are similarly mounted forward and aft in the same superstructure, while two other 3-pounders are carried on the top of each of the gun houses of the upper level pair of guns. On the main deck there are seven 4 7-inch guns mounted within the citadel of 9-inch armor on either side, and the arrangement is such that the guns can be trained through an arc of 50 degrees on either side of the center line transverse to the keel, so that they can be trained astern and ahead Altogether there are twenty-two 4 7-inch guns included in the secondary armament The result is that in action the vessel can pour a broad side from ten 12-inch guns firing 850-pound shells, eleven 4 7-inch guns firing 45-pound shells, and six guns firing 3 pounder projectiles. As all are of the latest quick firing type, a comprehensive idea of the formidable character of the attack of this vessel may be obtained

The gun-operating mechanism is electrically and hydraulically driven, electricity being used for training the turrets In addition there is emergency gear for every operation Immediately the gun is fired an air blast cleans it and the rammer is fitted with a water spray, so that in the event of any sparks remaining when the breech is opened they may be at once extinguished The accommodation for the personnel is most adequate and commodious, especially in regard to the officers' accommodation, and in view of the hot climate in which the vessel is to be in service, special attention has been devoted to ventilation. The navigating bridge has outer wings, which are also removed when the ship is cleared for action

The gunnery trials created unusual interest, and the representatives of several powers were present thereat The trials served to dissipate conclusively many apprehensions that had formerly been entertained For instance, there was considerable discussion as to what effect would be produced upon the gun crew in the lower barbette of the fore and aft 12-inch guns when the weapons immediately above were discharged In the first test the crew were withdrawn from the lower gun house when the upper pair was fired. It was found, however, that the roof of the lower house offered a complete protection against the blast, and that the crew could safely stay in the lower house without experiencing the slightest ill effects of the tremendous blast some five feet above their heads It was also considered that the principle of setting the fore and aft guns one above the other and at a distance of 36 feet center to center was objectionable, on the plea that the aiming of the upper guns would be interfered with by the flash from the guns just below, but here again practical trials dispersed any such objections These results, by the way, corroborate certain results obtained some years ago by our own Navy Department at Indian Head, when this system of mounting, first proposed and adopted in our "Michigan" and "South Carolina," was tested.

Cement for Aquaria – Equal parts flowers of sulphur, pulverized sal ammoniac and iron filings, mixed with good linseed oil varnish and adding enough white lead to make a solid, easily workable mass.

## THE FIRST METAL BRIDGE IN AFGHANISTAN

The accompanying illustration represents the Diroontah suspension bridge, the first metal bridge to be erected in Afghanistan, which was opened last year The structure spans the Kabul River at the mouth of the famous Diroontah Gorge about seven miles from Jallabad Prior to the erection of the bridge communication was maintained between India and the adjacent country by means of a primitive native ferryboat, or raft, composed of skins stretched taut on a framework of rough timbers, and lashed together by means of crude native-made rope A cable was stretched across the river, and when the latter was at its normal stage the raft was pulled from one bank to the other by this means When, however, the waterway was in flood, and the turbulence and velocity of the current prevented recourse to the rope, the raft had to be rowed across the river, an operation which required considerable dexterity with the primitive oars used The journey was somewhat dangerous under the circumstances and the opposite bank was only gained some considerable distance downstream Owing to the rude character of the ferryboat a capsize was by no means infrequent, and indeed several lives were lost from this cause every year

When it was decided to erect a bridge, the site chosen for the structure was just off the old Kabul road As the photograph shows, the gorge is extremely wild at this point, the rocky cliffs dropping straight down into the water. The contract was carried out under Mr J R Halliday by the Calcutta engineering firm of Messrs. Burn and Company, Limited

The bridge has a span of 396 feet between tower centers, with a clear width between parapets of 10 feet. It is designed for pedestrian and light vehicular traffic. The inaccessible character of the site combined with the fact that none but unskilled native labor was available, rendered the task somewhat difficult The abutments had to be blasted out of the solid rock, as did the roadway approaches on either side On the Jallabad side these preparations together with the setting of the foundation bolts were completed in seven and a half weeks Work then had to be suspended for seven months, as the services of the Afghan labor was required in Kabul Upon resuming operations, work was continued without further intermission and the bridge was erected in the actual working time of five months Considering the nature of the work, and that the native laborers were quite unacquainted with the tools used such a performance was highly creditable A further month however was occupied in blasting out a roadway and approach to the bridge in the cliff face on the Lagna side of the river The bridge was opened by His Majesty the Amir of Afghanistan amid much ceremony and before a huge crowd of natives, who lined the precipitous hillsides to witness the novel spectacle

*This graceful structure, recently completed, takes the place of a primitive rope ferry.*

THE FIRST METAL BRIDGE TO BE ERECTED IN AFGHANISTAN.

---

Until a few years ago, all public coal lands were valued uniformly at a rate of $20 or $10 an acre, according if they lie less or more than 15 miles from a railroad Since July 1906, the government has been appraising its coal land according to the value of its contained coal The present value fixed for the government coal land, based on the new regulation, is $149,772,443, the value fixed for these same coal lands before the new classification was adopted was $48 240,971 According to these figures, it is evident, therefore, that if these lands had been sold at the prices prevailing before July, 1906, they would have brought the government about $100,000,000 less than their value at the prices now fixed

## BIRDS AS MECHANISMS

BY B S BOWDISH.

The casual observer knows the birds as he knows the tree the stone or the sea shell—an incidental object of passing interest, one of the trivial details in his every-day life The novice bird student knows the birds, few or many species, by the clothes they wear so to speak If somewhat adept, he may even recognize birds by flight and song Even the more profound ornithologist classifies birds by external character—largely bill feet, length of wing and tail, number of feathers in each, etc He is of necessity a specialist paying particular attention to classification pterography or the study of plumage ornithological osteology or some one of the sub-divisions of the general study of birds Few individuals among any of the classes of students mentioned sufficiently appreciate the bird as a mechanism designed to play a certain part every member like every detail of some complicated and perfect machine contributing toward perfecting the whole for its requirements

Considering the bird from this standpoint and analyzing the parts with a view to their functions it seems natural to commence with the bill because it is the anterior extremity and because of the importance of its uses This one feature of a bird's mechanism merits treatment in an article especially devoted to it and has, in fact received such treatment.* It can be briefly reviewed only here The bill not only performs the functions of a mouth in birds, but also serves as a hand Having none at all on the posterior limbs, and only unsatisfactory substitutes on the anterior ones, birds must needs use the bill largely in lieu of a hand, and do so to a very considerable degree

As has been shown, the bill largely conforms in shape to the requirements of the more important functions that it must perform, and exhibits a very wide range of variety in size and shape It is used for cutting tearing, and chewing food of various sorts, and for seizing, spearing, or engulfing prey It is also used to dress the plumage, and by some species, such as parrots, to assist in climbing

Birds' skulls, having a less diverse range of functions than the bills, show a correspondingly smaller degree of differentiation, but they do vary to some extent according to the habits and particularly according to the orders In the lower types, such as grebes and loons, and most of the sea birds, the brain cavity is relatively small, but proportionately larger in the higher types, such as the thrushes including the robin

The vertebral portion of the skeleton plainly indicates the bird's descent from ancestral stock common with that of reptiles Modern birds being no longer provided with reptile-like tails, as was the case with the earliest types (the archeopteryx had twenty caudal vertebræ the bony structure of a long lizard like tail, each vertebra supporting a long feather on either side) the number of caudal vertebræ has become reduced to usually nine and these are short and with little apparent function, other than to support the feathers of the tail, fan like, about the outer bone

The bony structure of the wings is an adaptation of the bones of fore limbs to the requirements of flight In evolutionary history this adaptation was principally accomplished in the lizard like progenitors of birds and the modifications since then are not remarkable The main arm bone the humerus and the secondary ones the ulna and radius are not very different from the corresponding bones in mammals. In the hand, however, the first and fifth fingers have disappeared the index and third digits are small and scarcely functional, while the middle finger is greatly developed and furnishes the real bony support for the tip of the wing

Wings for the great majority of birds are solely organs of flight, in a few species such as the ostrich they are rudimentary and functionless serving at best only to preserve symmetry In such species as penguins, however, while useless for flight, they are valuable as flippers or paddles, assisting progress through the water In a very few cases they are used to assist the bird in climbing usually largely while immature, as in the hoatzin of South America

Next to the bills and wings the feet of birds are perhaps of the greatest functional importance Feet and legs vary greatly, according to the usage for which they are designed In the ostrich, which most nearly resembles in its mode of life some wild horse, the development of feet and legs is strikingly like that of the feet and legs of such animals Birds like the kingfisher and humming bird whose feet are used solely for perching have absurdly underdeveloped, small, and weak looking feet and legs In the birds of prey the feet are practically grappling hooks, designed to secure the firmest hold of the victims, the legs are heavy and strong Birds like the herons the storks, and cranes, who spend much time wading, have very long legs and long, slender toes, which, spreading over a wider surface, give a support analogous to that afforded by snowshoes This feature is more strikingly illustrated in birds like the rails, that travel about on the yielding aquatic growth, and finds its highest development in the jacanas, tropical and sub-tropical birds of the rail family Woodpeckers creepers, and nuthatches, birds that cling a great deal to perpendicular surfaces, have very sharp claws and feet adapted to such requirements. Birds that swim a great deal have the feet webbed with a membrane extending between the toes, making very efficient paddles

The flesh of birds is no less efficiently designed and disposed toward the fulfilling of the requirements of the birds than the skeletal structure. The more important muscles are peculiarly designed to render the greatest efficiency The powerful muscles that operate the wings have their anchorage on the keel of the breastbone, and the latter is particularly deeply developed in birds of most powerful flight. This is true alike of the man-of war bird, with its immense wing area to maintain spread for hours in sailing, and of the humming bird with its relatively small wings, driven at lightning speed to keep the bird poised before a flower

In all of the passerine or perching birds, the muscle and tendon arrangement of feet and legs is such that the weight of the body resting on and contracting the legs draws the muscle over the main joint, and draws up on the ends of the toes, locking their grip on the perch The same principle drives the talons of the hawks and owls into their prey

Tongues in birds are also highly functional In woodpeckers they are practically barbed spears, and the extreme protrusion that they are subject to is provided for by roots that extend around the back of the head and close up to the eye-sockets In the humming bird the tongue is a pump for obtaining the nectar from flowers. In some species it is brush like, to facilitate handling the food, and in certain fish-eating species the upper surface of the tongue is covered with points inclined backward, to facilitate swallowing the slippery prey

The eyes of owls, designed to see at night, are wonderful structures. Only a small portion of the entire eye-ball is visible Each socket occupies nearly a third of the total skull space The visible eye-ball is mounted on a thin bone frame, somewhat resembling a lamp-shade in shape, a structure differing radically from the type of bird's eye

The feathery covering of birds is especially adapted to their requirements It is light offering the least weight to be carried in flight, and a poor conductor of heat and cold, affording the bird the best protection in the sudden temperature changes to which it is subjected In birds like the penguins it is more like the hair of seals than normal feathers and is thoroughly waterproof The feathers of ducks and water fowl generally are also practically waterproof The power of flight is quite dependent on the feathers both of wings and tail which in action are spread to give the greatest supporting area for the air pressure to act upon

As a complete mechanism, so perfectly do all its parts contribute to an absolutely smooth-working whole, in the bird, that the very wonder of this intricate machine passes unnoticed as a common-place incident.

1. The bird's paddle, 2, the oyster catcher's bill 3, black skimmer's bill 4, bony structure of bird's foot 5 and 6, bill and foot of Cooper's hawk 7, vestiaria related to honeysuckles, 8, mamo's bill 9, heron's bill; 10, the osprey's foot, 11 cormorant's bill, 12, huia (male) related to starlings, 13, huia (female), 14 egret's bill 15 and 16, bill of drongo, related to shrikes, 17, bones of a bird's wing, 18, foot of a barnyard fowl; 19, foot and leg of rhea, South American ostrich

THE BIRD AS A MECHANISM

---

Metal filament lamps generally are supposed to be of a pretty frail nature, so that the slightest touch breaks them This idea is counteracted by an account given in the Electrical World of a collision between a Pennsylvania eastbound passenger train and an empty engine just outside Jersey City on the morning of November 8th This accident resulted in comparatively few injuries to the passengers, due to the fact that the strong frames of the passenger cars resisted crushing The damage to engines and cars, however was considerable. One of the steel passenger coaches jumped the track and turned over on its side, denting in the steel plates about 18 inches. Included in the lighting equipment of this car were nine tungsten lamps, and it is interesting to note that, after the wreck these lamps were found to be in perfect condition.

## EXPERIMENTS IN CRYSTALLIZATION

BY A. J. JARMAN

The making of crystals of various kinds outside a chemical works or chemical laboratory is not often practised, because it is commonly considered that the subject is a very difficult one or that it requires a complete knowledge of chemistry. Such, however, is a mistaken idea from either standpoint. Crystals of extraordinary beauty both in geometrical form and brilliancy of color can be produced by any person determined to make the undertaking successful.

The accompanying illustration shows a group of pyramidal crystalline structures that have been formed in the national colors.

The red is made of bichromate of potash, the white of common alum, and the blue of sulphate of copper.

Many salts can be employed that are very cheap, and after the crystals have been formed the solution left over can often be used. The geometrical forms of the crystals can be observed during their formation, and it is interesting to watch how they grow as the liquid deposits the excess of salt. When finished, they can be dried and preserved under a glass covering like wax flowers so as to preserve them for ornament and for educational purposes.

To produce results as illustrated make a pyramid out of three pieces of wood five inches long, and a quarter of an inch square. Wind each stick with cotton twine from end to end. Bind these three strips well at the apex of the pyramid and then for the base make a little triangle of the same sized strips, each piece being two and a half inches long. Cement these firmly at the corners with sealing wax, then cover every part neatly with a winding of cotton twine. Now distend the free ends of the three longer pieces, and fasten them to the base with sealing wax, after which carefully cover all the waxed parts with twine. For a fine pyramidal block of white transparent crystals prepare a small quantity of concentrated alum solution made by adding powdered alum to a pint of boiling water until no more will dissolve. Dip the cotton twine covered tripod or pyramid into this solution, let it soak for a minute, then stand it in a plate to cool. When cold it will be coated all over with very fine crystals of alum. This is the starting point to build up the final crystallization. Examine the minute crystals with a magnifying glass, when it will be seen that the face of each crystal is triangular in form, the corners being cut off. No matter how small or how large the crystal may be, it always assumes the same geometrical form, for every salt crystallizes in a form according to its nature.

Procure a two-gallon stoneware crock and a one-gallon glass battery jar. The battery jar should be eight inches high and six inches in diameter. Pour seven pints of boiling water into the stoneware crock. Add thereto about five pounds of powdered alum, a few ounces at a time, stirring the solution well with a clear strip of glass. As soon as the hot water will dissolve no more alum it is then saturated and must be poured into the glass battery jar, which has been previously warmed, straining the solution of alum by tying a three-fold piece of cheesecloth over the top of the jar. Now place in the battery jar a circular-like lid about ½ inch deep, such as the lid of a paste jar. Set upon this lid a piece of glass four and a half inches square and upon the glass the slightly crystallized pyramid completely immersed in the solution and weighted down with a large alum crystal or a heavy glass stopper. A small crystal of alum may also be placed upon the top of the pyramid. All must now be left to cool gradually. Under no condition must the vessel be disturbed, because this would cause the alum to be thrown down in a few minutes in very fine crystals like common salt.

At the end of twenty-four hours, the whole of the pyramid will be covered with beautifully formed crystals. At the end of forty-eight hours, the pyramid may be removed, and the alum solution made hot once more, adding more ground alum to saturate the solution; pour this solution again into the battery jar and insert the pyramid with the sheet glass base, allow this to stand for a week, when it will be found to have become a mass of beautiful crystals, clustering into one solid mass. The pyramid must now be removed (the glass plate also by a slight tap), a pint of clean, cold water poured over it, then stood upon folded blotting paper to drain, changing the blotting paper twice daily for a week to nine days, when it will be found that the crystals will become almost transparent. The pyramid being complete, it may now be covered with a suitable glass dome, and it will form a unique and instructive ornament. Several sets should be made from various salts, in various colors. All of them can be carried out in precisely the same manner as described for alum.

The following salts are not expensive and will give the various colors stated. They will not become moist upon exposure to the atmosphere. For white, common alum and cane sugar; red, potassium bichromate; yellow, yellow prussiate of potash; dark green, double sulphate of nickel and ammonia; light green, chlorate of nickel.

There are very many other salts that will give a great variety of colors, the majority of them being deliquescent, becoming moist and melting upon exposure to the atmosphere, but those enumerated here will be permanent under all ordinary conditions.

RED, WHITE, AND BLUE PYRAMIDAL CLUSTERS OF CRYSTALS.

## SIMPLE METHOD OF PRODUCING THE ZEEMAN EFFECT

BY W. K. CARR

The world was startled when a few years ago, Prof. Zeeman announced that if pieces of sodium were burned between the poles of a powerful electro-magnet the spectroscope would show the D line much broadened while the exciting current was turned on, and that the original aspect of the line would be restored as soon as the current ceased.

The experiment confirmed the much-discussed theory of H. A. Lorentz, who assumed that the hitherto homogeneous and indestructible atom of the chemist was, as a matter of fact, heterogeneous and composed of minute particles or vortices in the ether of space, having a definite mass and possessing all the properties of negative electricity. These particles, or vortices, which are now called "electrons," he conceived as vibrating about the common center of gravity of the atom, and further that light was due to transverse vibrations in the ether generated by these rapidly moving electrons. If, argued Lorentz, the atom be made up of such particles or vortices, their rate of vibration would be altered by the lines of force in a magnetic field, and we should be able to predict their behavior with accuracy. Going back to two swinging pendulums for analogy, he pointed out that any motion to which the electron is subject could be resolved into three components, one in straight lines parallel to the lines of magnetic force, and the other two at right angles to them, but since these last two can be further resolved into two circular motions (one to the right and one to the left) around an axis parallel to the lines of force, we can say that the motion which the electrons are capable of making may be divided into component number 1, in which the electrons are moving parallel to the lines of force; component number 2, in which they move with the hands of the clock, and component number 3, in which they move against the hands of the clock. Now suppose we look at the vapor of sodium in a magnetic field and along the lines of force. Consider the electrons as negatively charged, and the lines of force running toward you, what will happen? You cannot see any effect of component number 1, since the electrons of that component are moving in the line of your vision, and since electrons emit waves only at right angles to the line of sight, hence to see the waves of component number 1, you would have to move your position and look at the burning sodium at right angles to the lines of force. But with components numbers 2 and 3 the conditions are very different. Here the electrons are revolving in circular orbits and in a plane at right angles to the line of sight, and since those which move with the hands of a watch are retarded, and those against the hands of a watch are accelerated, the single line seen in the spectroscope would split into two, or, as in Prof. Zeeman's case, where the spectroscope was of small dispersive power, only a broadening of line would be observed. This, then, was the experiment which startled the scientific world, startled it because one of the fundamental principles of science was apparently overthrown—the homogeneity of the atom of the chemist.

Notwithstanding its value and significance, the experiment is rarely witnessed because of the ponderous and costly apparatus necessary to produce the division of the spectral lines. Powerful gratings and magnets, both exceedingly expensive, have up to the present time been used in the demonstration. The writer, however, has a very simple piece of apparatus costing less than $30, which shows the phenomenon admirably. No claim to originality is made save in the matter of its arrangement, which is so simple as to be well within the grasp of any intelligent boy. Instead of the powerful spectroscope the reader will observe in the accompanying photograph a little interferometer attached to the telescope. This is a modification of Fabry's, and for it the writer is indebted to the inventive genius and the exquisite mechanical ingenuity of Prof. Pfund of Johns Hopkins University. And instead of the huge magnet used by Zeeman, one weighing less than forty pounds is found more than ample. The photograph shows a piece of board six inches long to which is attached *A*, a lens of three inches focus, *B*, a Nicol prism which can be revolved in its brass collar, *C*, the interferometer, *D*, the telescope, and *O*, a spring clip for holding the quarter wave plate. This apparatus is simplicity itself, is always in adjustment, and can be rapidly shifted to view the phenomenon along the line of sight and at right angles to it.

Instead of burning sodium, let us use a tube containing helium gas, and place the apparatus so that we may view the light parallel to the lines of force and through the hole drilled in the pole piece of the magnet, as seen in Fig. 1. Examine the glowing tube before the magnet is energized and you will see several concentric yellow rings in the field of the telescope.

Fix your attention upon any one of the rings which is the equivalent of the yellow line that would be seen in an ordinary spectroscope. Turn the current into the magnet, and instantly the yellow ring splits into two. Revolve the Nicol, but you cannot extinguish the rings because, just as Lorentz predicted, they are circularly polarized. Now introduce a quarter wave plate, the effect of which is to produce a retardation of one-half wave length. The light is now plane polarized and can be extinguished by the Nicol—a further and a beautiful confirmation of Lorentz's theory. So much for components numbers 2 and 3, but component number 1 cannot be seen since its electrons are moving parallel to the lines of force. Now take out the Nicol and move the apparatus so as to view the light at right angles to the lines of force (Fig. 2). Turn on the current and one yellow ring is observed to break up into three. Let us analyze them, bearing in mind what Lorentz said, viz.: That one of these lines, component number 1, was polarized lying in a horizontal plane, and that the other two, components numbers 2 and 3, were polarized in a vertical plane; vertical because in this position we are looking at the edges of these circular vibrations, and the effect upon us is as if the particles were actually moving vertically. Now introduce the Nicol with its short diagonal vertical, two rings appear, and with the short diagonal horizontal one ring appears, a beautiful confirmation of one of the cleverest pieces of reasoning ever credited to the mind of man.

In the whole realm of physics there is nothing more

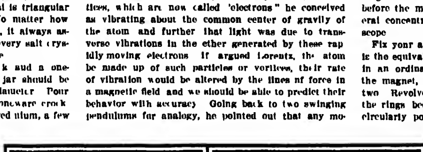

Fig. 1.—Looking in the direction of the magnetic lines. Fig. 2.—Looking at right angles to the magnetic lines.

APPARATUS FOR PRODUCING THE ZEEMAN EFFECT

striking, more significant, and the effect which it is destined to exercise upon the future of science is simply incalculable

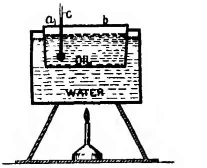
### SOME SIMPLE TESTS FOR OILS.

BY RALPH P CLARKSON

There are several tests which anyone can apply without the use of special apparatus, and tell something about the grade of lubricating oil he is getting

THE FLASH TEST

Place a small amount of the oil to be tested in a



APPARATUS FOR DETERMINING THE FLASHING POINT OF OIL.

pan as indicated at *a* in the accompanying engraving, and heat by means of the lamp beneath As the oil heats apply a match at *b* After a time a flash is seen when the match is applied, but it disappears as rapidly as it came This shows that enough vapor had been produced to mix with the air and form an explosive mixture The temperature, given by thermometer *c*, at which this occurs, is called the flashing point. At some higher temperature if a match is applied, the oil takes fire This latter temperature is known as the burning point, and may be a considerable number of degrees above the flashing point.

TO DETECT THE PRESENCE OF AN ACID.

Dissolve a small amount of sodium carbonate in an equal volume of water Place it, together with the oil to be tested, in a flask or beaker and shake thoroughly The quantity of precipitate will be a gage of the amount of acid present.

TO DETECT THE PRESENCE OF GRIT

Drop a small amount of the oil on white or very light-colored blotting paper The oil will be absorbed, and the grit will be visible as small black specks on the blotter

TO FIND THE TEMPERATURE AT WHICH THE OIL CONGEALS

Put 15 parts of Glauber salts into a beaker Place in this a bottle containing a sample of the oil. Place over the salt a mixture of 5 parts hydrochloric acid and 5 parts of cold water The temperature is reduced slowly, and can be observed from time to time as the oil thickens Any freezing mixture or even ice can be used in place of the above

### THE IONIZATION OF AIR.

SOME SIMPLE EXPERIMENTS

The terms ions and electrons have now become familiar in the explanation of electrical phenomena Most of the investigations upon which they are based how ever have been made *in vacuo*, and consequently they are but little understood, except by those scientists who have devoted their energies to their especial study There are however many simple experiments, mostly due to Righi, which can be made in air at the ordinary pressure, and which form a useful introduction to the study of ionization The accompanying illustrations represent some of these typical simple experiments performed by Mr C J Watson of Birmingham, which aroused considerable interest at a recent scientific *conversazione* in that city, and through his courtesy we are able to explain how they were carried out and how they may be repeated by any interested reader

It is well known that if a pointed wire be connected to one pole of an influence electric machine, and the other pole is earthed, a discharge of electricity will be obtained The proof of electric discharge may be easily verified by means of a lighted candle and a gold-leaf electroscope If the former is placed on the cap of the latter, the electroscope, even if disposed several yards from the machine, will collect continuously the electricity discharged from the machine Similarly, if the action is carried out in the dark, a small stream of purple light may be seen, which although scarcely visible, will exercise a pronouncedly marked influence upon an exposed photographic plate Another method in which this discharge may be ascertained is to place a condenser, comprising a piece of glass 1/16 inch thick coated on both sides with tinfoil to within ½ inch of its edge, opposite the point of the wire Then connect the two opposite coatings of tinfoil with a strip of the same material, which has a fine cut in it When the reverse side of the condenser is connected to earth, there will be a distinct spark jumping across the narrow gap

If this discharge point then be immersed in a metal box fitted with an opening which is covered with perforated zinc, so that the electrified air is forced through the perforations, if the box is earthed it will be found that the air which is thus expelled is totally deprived of electric charge It thus appears that the

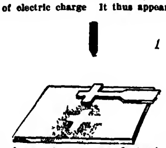


Fig. 1.—Interposing a non-conductor in the path of the ions.

electric charge is not carried by the particles of air generally, but by a smaller number of what for the present are generally described as ions.

Several simple experiments may be carried out to ascertain the paths pursued by these ions For instance, take a sheet of ebonite the reverse side of which is coated with tinfoil and earthed, and place it a foot distant from the discharge point. It is advisable to pass the sheet over a gas flame for a few seconds before each experiment, so that any electricity present in the sheet may be eliminated When the discharge from the electric machine is carried out for about one second, the sheet will be charged sufficiently No visible effect of this occurrence will be observable; but if the sheet is sprinkled with a mixture of powdered red lead and sulphur, and the same experiment is repeated with an obstacle of non-conducting material interposed between the discharge point and the sheet, such as say a cross, an image of that object will be produced upon the plate. If negative electricity has been discharged from the electrical point, then the sulphur will collect on those parts

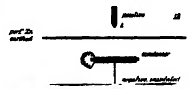

Fig 12.—Forcing a discharge through a zinc sieve.

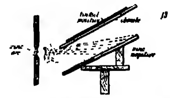

Fig 13.—Effect of ultra-violet rays on zinc.

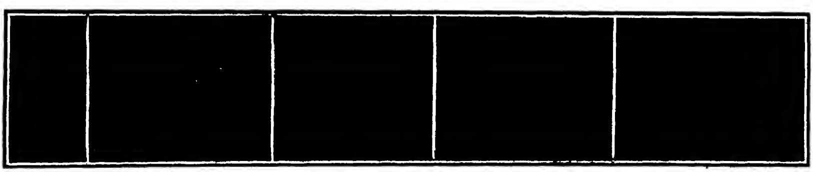
immediately beneath the object, while the red lead will adhere to those parts charged negatively by the unimpeded discharge on the surrounding areas The drawing, Fig 1, shows how the experiment is carried out, while the photograph, Fig 2, gives the result of the interposition of the cross in the path pursued by the ions

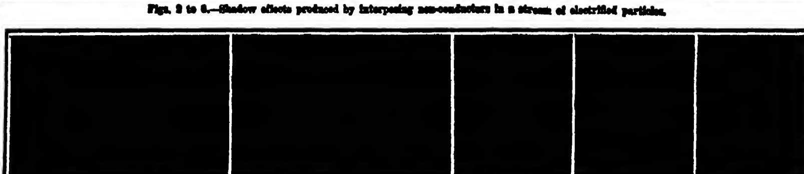
The image of the object is usually enlarged, but this factor is influenced to some extent by the length of time of the electric discharge A preferable method is to take a sheet of celluloid, as shown in Fig 3, perforated with holes at regular distances Then when the image of these holes is obtained, as shown in Fig 4, the distances between their centers can be measured When the distance of the ebonite sheet is varied (the distance of the celluloid sheet from the electric pole being kept constant) it will be found that the size of the image grows with the distance, but not proportionately The electrified particles or ions travel along the lines of electric force, and consequently generally in curved lines This has been proved by using, instead of a point, a long thin wire held parallel to the interposed sheet of celluloid when the lines of force are circular arcs passing through the wire, and striking the ebonite perpendicularly to its surface

It will also be found that the streams of ions mutually repel each other, so that if the electrified point be very near to the celluloid, the individual images of the holes will be found to have enlarged themselves at the expense of the intervening spaces and will even be observed to have assumed almost a square form, as shown in Fig 5 This is of course analogous to what is observed with the cathode rays of highly exhausted tubes. A similar repulsion is also manifested when an insulated metal object is used as the interposed object This is illustrated in Fig 6 which represents the effect produced by a piece of brass tubing on the end of an ebonite rod, both being of the same diameter

(Continued on page 250)



Figs. 2 to 6.—Shadow effects produced by interposing non-conductors in a stream of electrified particles.



Figs. 7 to 11.—The effect of an air blast on the discharge, and of forcing a discharge through perforated zinc.

THE IONIZATION OF AIR.—SOME SIMPLE EXPERIMENTS.

## RECENTLY PATENTED INVENTIONS.

### Electrical Devices.

TELEPHONE-MUFFLER.—W D. Plums, New York, N. Y The invention relates especially to a device the purpose of which is to increase the distinctness of sound produced by the receiver, the operation of the device consisting in muffling or dampening the sounds which may be produced sympathetically or otherwise in the diaphragm of the transmitter

PLUG FOR ELECTRICAL CONNECTIONS.—A N Dodd, Mount Vernon, N Y The improvement has reference to plugs for electrical connections, the inventor's more particular purpose being to provide a construction suitable for plugs of large size and used in connection with powerful currents such as characterize automobile charging, theater dimmers, and the like

### Of Interest to Farmers.

MACHINE FOR COLD-ROLLING DISKS.—A L Dow, Grover Colo. The aim of this invention is to provide a device which is of light weight so that it may be carried about from place to place It is so constructed that it can be carried into the field and readily attached to an engine used to reciprocate a plow, to drive the same It relates to machines adapted to sharpen and roll disks used in plows, disk harrows, seeders, drills, etc

HAY FORK.—E. Swan, Elko, Nev The invention relates to a hay fork of the grapple type, which is adapted to lift a large amount of hay, to unload the same from a wagon, and which is also adapted to readily deposit the said hay on a mow or stack It is quick and positive in action, and strong and durable

### Of General Interest.

APPARATUS FOR PRINTING WOOD GRAINING AND THE LIKE.—J E Currert and W J Wesley, Erie, Pa More particularly the invention pertains to a device adapted to be moved over a surface and print or produce thereon the semblance of wood graining The main object is to so construct the apparatus that it may be used in producing a graining or printing on any stationary well irrespective of its shape or position

STERILIZER AND WATER HEATER.—A. R Talbott, Ellis, Kan In this case the invention refers to sterilizers and water heaters especially designed for dentists use, and the object is to provide in convenient form and at little cost, a device which will thoroughly sterilize instruments with boiling water, and will at the same time, heat water for cleaning the mouth

VIOLIN SUPPORTER.—H A Smith, Danbury, Conn The purpose of the inventor is to provide features of construction for a violin support, which are convenient in service afford perfect freedom in handling the instrument, permit the quick easy connection of the violin with the supporting device and its release therefrom as may be desired

BOAT FLOORING.—F Schmidt, New York, N Y For the purposes of this invention, a cushioned flooring is placed on a support in the vessel in such a manner that it is completely out of contact with the hull or other part of the vessel, so that the vibrations are absorbed by the cushion, and hence are not felt by the persons standing or seated on chairs set on the flooring.

### Hardware and Tools.

RAZOR STROP.—A L. Silberstein New York, N Y The strop is more especially designed for use in stropping thin razor blades, of the Gillette and other types, without much exertion on the part of the operator For this purpose the rocker of the strop is adapted to receive a removable blade holder having retaining means for holding the razor blade in position It relates to safety razor strops such as shown and described in Letters Patent of the U S, formerly granted to Mr Silberstein.

TOOL-HOLDER FOR PNEUMATIC HAMMERS.—V R. Lane, Berwick, Pa The most particular purpose here is to provide a construction adapted to the hammer, allowing the tool all necessary freedom and effectively preventing the tool from being unexpectedly ejected from the hammer so as to cause an accident

Note.—Copies of any of these patents will be furnished by Munn & Co for ten cents each Please state the name of the patentee title of the invention, and date of this paper

# INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending March 8, 1910,

AND EACH BEARING THAT DATE

## NEW AEROPLANES.

(Continued from page 236)

weight of the machine complete is about 400 pounds The thrust obtained from the propeller at 1,200 revolutions is in the neighborhood of 200 pounds. The double surface horizontal rudder is carried upon hollow inclined poles some 12 feet in advance of the main surface, and the single surface tail is similarly carried at the rear The machine is mounted upon a central runner having two smaller skids at each side There is also a skid at each end of the lower plane

The novel features of this machine are the foot control of the horizontal rudder, and the system of triangular vertical fins on the top of the upper plane for the purpose of maintaining the transverse stability automatically The aviator sits upon a small seat located in front of the lower plane and clings to two inclined braces running out in front to vertical struts connecting the poles that hold the horizontal rudder These inclined braces can be readily seen in the photograph as well as the pedals for the feet of the aviator which operate the horizontal rudder The vertical rudder is worked by a small lever held in the aviator's right hand, and the spark and throttle control of the motor is also conveniently placed

The theory upon which the transverse fins (each of which has about 2 square feet of surface) operate in order to maintain the transverse stability of the machine, is as follows When the machine tips to one side it has a tendency to slide down toward the ground endwise, but as the weight is placed very low and as the fins offer resistance to this side motion the upper part of the machine is retarded, while the lower part swings over like a pendulum, and the machine regains an even keel

In the first trial the surfaces (which are of special paraffin-coated silk) were very loose owing to fog and dampness, and once the machine was in the air it was necessary for the aviator to sit well over to the left side, in order to counterbalance a difference in lifting power of the two sides of the machine The biplane rose readily after a run of about 85 feet The machine is said to have lifted at a speed of about 22 miles per hour The horizontal rudder was turned too far and the machine shot up to a height of 40 feet at an angle of nearly 30 degrees Mr Herring attempted to make a turn after flying some 300 feet, and the machine turned successfully tipping inward at an angle of about 20 degrees from the horizontal and making a 40 degree turn He then cut off the spark and descended In alighting the seat was split and a runner and one of the inclined rods were broken According to the inventor, the machine rose in the air with the aviator (who weighs 190 pounds) with a thrust of 140 pounds, and he believes that a thrust of 80 to 85 pounds is sufficient to fly it The throttle was not fully opened, and the motor, he thinks developed not more than 9 horse power when the machine was in flight

This biplane is the first aeroplane to fly in New England but it is principally noteworthy because of the new method of automatic stability which apparently seems to work fairly well

Mr Herring has replaced the vertical partitions of the Voisin biplane (which connect the main planes at the ends and at various points in between) by the six small triangular fins shown If these small fins, placed above the upper plane, answer the purpose as well as do the partitions in the Voisin machine, one can readily see that they offer much less resistance and skin friction to the air, and should make a much faster machine They form a means of automatic stability which is a decided improvement over warping wings or movable wing tips

(Continued on page 247)

# AMERICAN HOMES AND GARDENS

## CONTENTS FOR MARCH, 1910

(Continued from page 246.)

CAPT BALDWIN'S BIPLANE.

One of our illustrations shows the new biplane of Capt T A. Baldwin, the dean of practical American aeronauts. This new biplane has a number of original features, chief of which is the method of preserving the transverse stability by means of a single vertical stability rudder placed above the upper plane. This rudder is turned about its vertical axis by means of a fork fitting around the aviator's shoulders, as in the Curtiss machine When the aeroplane tips to one side or the other, by leaning to the high side the aviator sets the stabilizing rudder at an angle to the line of advance This exerts sufficient force to bring the machine back to a level keel The new stabilizing rudder is the outcome of experiments tried several years ago by the Aerial Experiment Association It has been tried out by Mr Curtiss, who claims that it worked satisfactorily upon his machine

The new biplane has a spread of 28 feet by a fore-and-aft width of planes of 5 feet which makes an area of 280 square feet of the main planes In addition to these there is a small biplane tail carried on a triangular frame extending back from the main planes and mounted upon a light skid The vertical rudder is placed in the center of this tail which forms in reality the horizontal rudder, since the two surfaces are moveable and are used to direct the machine up or down

The arrangement of the power plant and aviator's seat is just the opposite of the usual arrangement, and is along monoplane lines The motor is at the front edge of the lower plane and the aviator's seat above the rear edge The fly wheel of the motor extends below and above the plane The propeller is placed half way between the upper and lower planes and is driven by chain from the motor It is a large, high pitch propeller of between 8 and 9 foot diameter

The aeroplane is mounted upon two pneumatic-tired wheels in front and a single skid at the rear The regular Curtiss single-wheel control of the rudders is fitted The machine has had several successful tests upon the frozen surface of Lake Keuka, at Hammondsport, N Y

THE BLERIOT 1910 MODEL MONOPLANE.

The latest model Bleriot monoplane known as the "No 11 *bis*" is shown from the rear in one of our illustrations on page 236 As can be seen at a glance the body of the machine is now completely covered, while a new form of tail resembling that of the Antoinette monoplane has been fitted The horizontal rudder is in two parts hinged at the rear edge of the tail proper The spread of this new model is 7 2 meters (23 6 feet) the wings being about 11 x 7 feet in size and having an area of 12 square meters (129 6 square feet) The length of the body has been reduced from 7 to 6 6 meters (21 64 feet) The total weight is 310 kilogrammes (682 0 pounds), or with aviator 832 pounds This means a lift of 6 45 pounds per square foot of the deeply curved surfaces The highest lift per square foot heretofore obtained has been 5 pounds, so M Bleriot has apparently improved his machine in this direction although he has not diminished its weight but instead has increased it in order to give it greater strength The same 3-cylinder, fan shaped Anzani 25 horse-power air-cooled motor is used as heretofore This motor develops its power at 1 400 revolutions per minute, at which speed it revolves the 6 82 foot Chauvière propeller The pitch of the propeller is nearly half its diameter and the thrust obtained about 200 pounds. This new model is operated the same as his previous machines by a universally jointed control column pushed forward or pulled backward to direct the machine down or up, while it is moved sideways to warp the wings and correct the transverse equilibrium

SIR HIRAM MAXIM'S AEROPLANE

BY R. F. HEARNE.

Authentic details are now available

(Continued on page 248.)

(*Continued from page 247.*)

concerning the aeroplane which Sir Hiram Maxim has built at Crayford, Kent, England. No small degree of secrecy has been maintained, but to those who are acquainted with Sir Hiram's theories, it was evident that he would base the present aeroplane on the main principles which governed the design of the remarkable machine which he built and tested at Baldwyn's Park in 1894.

The present machine is the outcome of his original researches and of plans developed during the last five or six years but not until 1908 was the veteran inventor able to devote himself fully to the planning of a new flying machine. He also set himself designing a gasoline motor, as he held the idea that much of the trouble with the present aeroplanes was due to the unsuitable engines employed. Sir Hiram has now evolved a flying machine in which every portion from engine to propellers has been constructed according to his own ideas. His first care was to reduce the proportions of the machine as compared with those of the gigantic apparatus which he constructed at Baldwyn's Park. The total width of the new aeroplane is 44 feet, while his earlier multiplane had a span of over 100 feet.

Like its prototype, the new aeroplane is of the multiplane type, and is in effect made up of six aeroplanes, each being 6 feet 6 inches in width, fore and aft. The planes are notably thin, and are neatly covered with waterproof silk fabric very tightly laced. From the central plane spring out two superposed wings, raised well above it, and so curved as to produce automatic lateral stability to a very high degree. There are balanced rudders fore and aft, and a horizontal steering rudder. The Maxim patent device for varying the pitch of the planes when in flight is utilized. This differs from the Wright warping device. The wings are moved in one direction by a lever worked by hand, while a spring controls them in the reverse direction.

The engine is mounted between the planes, and behind the pilot, who sits in a low metal-covered compartment with the steering and control wheel in front of him. This disposition gives a very clear lookout, and at the same time the aviator is better protected from the wind. A highly novel feature is the propelling gear. On the engine shaft is one small screw propeller mounted at the rear of the planes. This screw travels at the same rate as the engine shaft, and serves also as a flywheel. There are two larger propellers each 11 feet in diameter, mounted higher up between the planes and driven by cables whose tension is controlled by jockey pulleys. The small screw and one of the large ones rotate in the same direction, the other large one in the opposite direction. This screw is also given a finer pitch and higher velocity than its companion, and in this way its gyroscopic action balances the joint gyroscopic action of the two propellers, which rotate in the reverse direction. This arrangement of the screws is as ingenious as it is novel.

In the engine, too, Sir Hiram has shown how closely he has studied every phase of the problem. He has selected a special brand of Vickers steel as the material for his 4-cylinder 60-horse power motor, and has been enabled to reduce weight while leaving a good margin of strength. Special care has been given to the carbureter and the valves. Sir Hiram claims that his engine works with far greater regularity and smoothness than the average aerial motor used on the Continent. The engine is fully water cooled and the radiator is mounted under the upper plane in a manner suggestive of that adopted by Santos Dumont on his little monoplane. A most ingenious system of automatic forced feed lubrication is employed,

(*Concluded on page 249.*)

(*Continued on page 2[illegible].*)

(*Concluded from page 248.*)

which carries oil to every working part of the engine in a very effective manner. Indeed, the new motor promises to set a splendid example in aeroplane engineering, for it shows that, by skillful designing and the choice of suitable material, a light motor can be built with all the refinements which are now usually fitted to high-grade engines for motor-car work. The spasmodic action of many aeroplanes at present in use is due largely to the fact that their engines are unreliable.

The new Maxim aeroplane is mounted on wheels fitted with neat shock absorbers. Regarding the machine as a whole, its clean lines and uncommon aspect are the most striking features. There is a noteworthy absence of the complication of stays, guy wires and framework, which on many biplanes cause so much head resistance. The grouping of the various organs has been very skillfully done, and as far as possible those parts which set up most resistance are set in the same lines, one behind the other, thus minimizing wind resistance. In effect the whole machine bears evidence of remarkable originality, both in its general form and in its main details. Sir Hiram does not yet propose to test it in free flight, as he has built an apparatus like that designed by the late Capt. Ferber, whereby the machine can circle in a captive state around a steel mast. When so many other machines, however, are experimented with in free flight by aviators of small experience, the Maxim method may not seem altogether necessary, although with a striking new type of machine it is undoubtedly a very sure course of procedure.

### THE OLIVE BRIDGE DAM

(*Continued from page 238.*)

cubic yards of rock excavation and 7,200,000 cubic yards of embankment and refilling. The plant of the contractor at the Olive Bridge dam consists of four cableways, about 95 feet in height, which extend across the valley above the dam with a clear span of 1,530 feet. The crushing plant, with a capacity of 200 tons of crushed stone per hour, and the concrete mixing plant are located conveniently to the work, the material being brought below the cableways, by which it is deposited as desired along the structure. Work was begun in the fall of 1907, and at the present time about 25 per cent of it has been completed.

The total length of the aqueduct (which is 17½ feet wide by 17 feet in height) from the Ashokan reservoir to the city line is 92½ miles, and its cost will be about $45,000,000. To render the work perfectly secure and permanent, wherever the aqueduct encounters streams or rivers of any magnitude it is carried beneath them either by deep pressure tunnels, or by steel and concrete pipes. The most notable pressure tunnel will be that below the Hudson River. In some respects this is the most interesting feature of the work, and we are informed by Mr. Alfred D. Flinn, Department Engineer of the Board of Water Supply, that the borings have revealed at great depth a granite rock eminently suited to carry this great and important conduit. In addition to a vertical boring made from a barge at the center of the river, which has reached a depth of 708 feet, two diagonal borings have been made one from either shore of the river. That from the eastern shore descends at an angle of 44 degrees for a distance of 1307 feet, where it has reached a point 70 feet from the center of the river. From the west shore, descending on an angle of 38 degrees, another boring has been driven for 1780 feet, which is now within 150 feet of the center of the river. The vertical shafts are now being sunk on either shore; they will be carried down to a depth of 1,200 feet below mean high-water level of the Hudson River at

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES

CAPITAL WANTED to defray costs of getting on market. New invention. Safety pin all wire, complete safety pin very simple. One patent secured, more applied for. Chas Burbland Jarlsberg, Ontario, Canada.

Inquiry No. 8918.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

THE PROPRIETOR of American Patent No. 872,018, November 1907, for an improvement in the filtration of water supplies, invites correspondence with a view to the sale or development of same. The principle of this invention has been favorably commented upon by the technical press of both continents. Address J. Grant MacGregor, C. E., Red Deer, Alberta, Canada.

## PATENTS FOR SALE

FOR SALE, Outright or on Royalty.—Match Box U. S. Patent No. 944,756. By pressure of finger it lights, presents and drops match without opening box. For full particulars address J. J. Willingham, 1a Hospital No. 20, Mexico City, Mexico.

Inquiry No. 8987.—Wanted the manufacturers of the Van Winkle Woods & Sons and the Weber power meters.

FOR SALE. U. S. patent rights to highest bonafide bidder April 2, 1910, telephone muffler. Telephone booths no longer necessary. See patent, March 12th issue. W. D. Plumb, 322 Lexington Ave., N. Y.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

FOR SALE.—Patent No. 916,860, Combined strainer and air cushion, for supply pipes to plumbing fixtures, catches all substances large enough to injure valves. Simple, neat. Fred A. Lewis, Box 112, Eldorado, Kans.

Inquiry No. 9016. Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

FOR SALE OUTRIGHT. Ladies' Sanitary Belt. Retails twenty five cents. Vast profit. Article marketed. Splendid mail order medium. Have made fortune. Patent eleven years to run. Strictest investigation. Arthur Lamm, 133 W. 85th St., New York City.

Inquiry No. 9018.—Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

FOR SALE.—Double carnation support. U. S. Patents Nos. 921,671-918,671, is the very best on the market; can be manufactured at low cost; large field for it. Will sell account of other business, with complete machines. Very reasonable. Address D. A. Muller, Ambler, Pa.

Inquiry No. 9020.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

## PATENTS WANTED.

AUTOMOBILE ACCESSORIES of practical value wanted by us to manufacture and market, either on royalty or purchase. Send description and terms. Address Royalty, Box 773, New York.

Inquiry No. 9026.—Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

## HELP WANTED

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres., The Nat'l Co-op. Real Estate Co., Suite 378, Marden Building, Washington, D. C.

Inquiry No. 9038.—Wanted the address of the Chipman Electric Purifying Co.

WANTED, young man, technical graduate in physics and chemistry; knowledge of optics also desirable. Splendid opening and opportunity for right man. Address M. M. Co., Box 773, N. Y.

Inquiry No. 9043.—Wanted the address of Farney Safety Razor Co.

## FOR SALE

FOR SALE. Engine lathe. Our regular $75.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $43.50. L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9052.—Wanted address of firms who install plants to manufacture nitrogen.

FOR SALE.—20 horse power Harris-Corliss engine in perfect condition. The reason for selling, mill business discontinued. Address The Elm City Lumber Co., New Haven, Conn.

Inquiry No. 9055.—Wanted address of parties interested in Log Cleaning Machines.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9060. Wanted to buy machinery to manufacture seed corn racks.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9066. Wanted complete outfit for export for making rice flakes and wheat flakes.

Inquiry No. 9068. Wanted to buy machinery for manufacturing chewing gum, such as rolling, cutting or wrapping machinery.

Inquiry No. 9069.—For the address of firms making chain cloth, something like ladies' purses are made of.

Inquiry No. 9071.—Wanted, the address of parties making moulds for large concrete vases for flower pots.

Inquiry No. 9072. Wanted machinery for making fine chains, such as used by jewelers, etc.

Inquiry No. 9073.—Wanted machinery to manufacture cocoanut oil; also the crude material.

Inquiry No. 9074. Wanted, to buy old model locomotives or steamboats, such as were exhibited with nickel in-the-slot attachments in ferry houses, etc.

A printed copy of the specification and drawing of any patent in the foregoing list or any patent in print issued since 1863 will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

(Concluded from page 249.)

this point. At that depth they will be connected by a horizontal tunnel. The aqueduct passes through the mountains, and reaches the westerly shore of the Hudson River at an elevation of 400 feet above tide level, and here vertical and horizontal shafts will connect with the 1,200-foot deep shaft at the immediate edge of the river, making a total depth of 1,600 feet from the flow line to the lowest level of the siphon. It is gratifying to realize that after the doubts and anxieties regarding the geological conditions affecting this work, its construction in solid granite has been assured. It should be mentioned that the whole siphon will be lined throughout with concrete.

At Kensico there is being built an auxiliary storage reservoir of about 40 billion gallons ultimate capacity, of which about 20 billion gallons will be available at flow line level. The elevation of the discharge will be 355 feet above mean tide. At Scarsdale, 4 miles south of Kensico, will be a large filtration plant, and at Hillview, 6 miles to the south of this will be built another storage reservoir with a capacity of 930 million gallons, the discharge being 295 feet above tide level.

The Kensico dam, which will be built across the valley of the Bronx, will be a masonry structure 290 feet high and 1830 feet long.

From the Hillview reservoir water will be carried to the several boroughs of the city in a pressure tunnel excavated deep down in the rock beneath the boroughs of Bronx and Manhattan and under the Harlem and East Rivers, to a point in the heart of Brooklyn, where it will be brought to the surface and continued in metal pipes, one branch leading north to the borough of Queens, and the other passing below the Narrows to Richmond at a point where the width is about 10,000 feet. The construction of this tunnel will confer the inestimable advantage that even at the lower end of Manhattan the water will rise to a height of 260 feet above sea level, or say to about the top of a 20-story building.

The total cost of the work from and including Ashokan dam to the city line, all of which is now under contract, is $69,094,870, and of this amount work to the value of $10,000,000 has been completed. The total cost of the whole scheme when all the watersheds have been developed, will be $162,000,000.

### IONIZATION OF AIR

(Continued from page 244.)

The metal becoming charged gives a greatly enlarged shadow.

The ions travel in a strong electric field at the rate of several thousand feet per second, and it is not the air which conveys the charge, although it is dragged along by the ions in the same manner as it is by a jet of water. This can be demonstrated very easily by directing a blast of air at right angles to the path of the ions. Scarcely any deflection of the latter occurs. For instance, in Fig. 7 is shown the image of an ebonite rod and a glass tube produced in the manner already described. The next illustration represents the same objects with a strong blast of air thrown athwart the course of the ions. The effect of the blast is only shown issuing from the tube just beneath the rod. Otherwise the result is exactly the same as if there were no blast.

The experiments may be varied within a very wide limit, and an interesting variation is to use, instead of the ebonite sheet, a plate of metal well insulated and connected to the other pole of the electrical machine, instead of earthing the pole as previously described. On the sheet of metal lay a piece of paper, and upon this sprinkle filings, preferably a mixture of magnesium and black iron oxide. Between the sheet and the discharge pole, interpose an object as before, such as the cross, and when the

(Concluded on page 251.)

(Concluded from page 250)

electrical machine is set in action the filings will disappear from under the ebonite cross, giving a well-defined image, as shown in Fig 9

In the early part of this article it was pointed out that the electric discharge would not pass through perforated zinc under the circumstances there prevailing But it can be made to do so To bring about this result place a plate of metal connected to the second pole of the machine beneath the ebonite sheet in such a way as to bring it opposite the discharge point *A* in Fig 12 Sprinkle the surface of the ebonite sheet with the powdered red lead and sulphur, and interpose an earthed sheet of perforated zinc or a metallic sieve between the discharge point and the ebonite When the electrical machine is set in action a perfectly defined image of the perforations of the zinc obstacle will be obtained upon the ebonite sheet as shown in Fig 11 If the plate condenser with its connected sides of tinfoil, mentioned previously is used, the passage of the ions through the perforations may be ascertained by the sparks jumping across the narrow gap The explanation is that under the conditions described the electric field extends uninterruptedly from the point of discharge to the insulated metallic plate, so that the perforated sheet is in a perfectly neutral condition and scarcely intercepts the ions.

Several other striking and interesting methods of ionizing air can be carried out, such as by a flame white-hot metals, electric sparks, and so on One of the most impressive is that showing that ionization is produced by ultra violet rays falling upon zinc If a plate of clean zinc connected to a gold leaf electroscope be negatively electrified and illuminated by the light of burning magnesium, or better still by an electric arc between zinc electrodes it is rapidly discharged If the charge is positive, the phenomenon will not be produced. The experiment will also serve to show that these negative ions follow the definite paths of the lines of force The illustration, Fig 13 shows how to carry out this experiment The tinfoil backing of the ebonite plate is connected to the positive pole of the machine Opposite this plate and parallel therewith is placed a sheet of zinc, connected to the negative pole of the machine leaving a clear width of about three inches between the two plates. The zinc plate is illuminated by the ultra violet light from the zinc arc light for about a minute Under these circumstances the lines of force run perpendicularly between the two plates, and if any design is painted in varnish upon the zinc plate, the emission of ions from that portion of the zinc will be arrested and a reverse image of the design will be obtained on the ebonite plate when subsequently dusted with the powdered red lead and sulphur mixture

---

The experiments of Sainte-Claire Deville and Caron apparently proved that the Oriental sapphire owes its beautiful color to the presence of a minute quantity of chromium in a state of oxidation lower than that which corresponds to the sesquioxide. It has not hitherto been found possible to reproduce the blue color with the aid of chromic oxide and reducing agents, nor yet to obtain by fusion in the oxyhydrogen flame, artificial sapphires colored by traces of oxide of iron If however, a small quantity of titanic acid is added together with the oxide of iron, the reduction of the acid to titanium oxide takes place to such an extent that the mass fuses and assumes the fine blue color of the sapphire This result has been obtained by Verneuil, who is of the opinion that in addition to sapphire colored by oxide of chromium there is another variety which owes its color to oxides of iron and titanium We have seen specimens of these artificial sapphires and to us they seem as beautiful as those of nature.

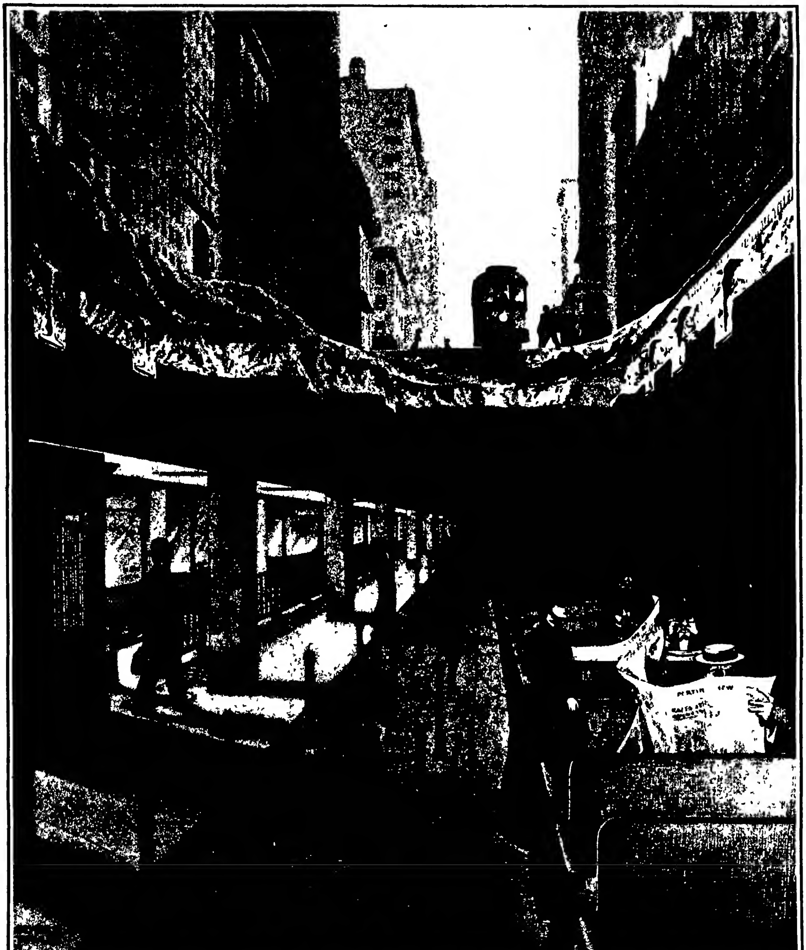
A POPULAR ILLUSTRATED WEEKLY OF THE WORLD'S PROGRESS

Vol. CII.—No. 13. | Established 1845. | NEW YORK, MARCH 26, 1910 | 10 CENTS A COPY. $3.00 A YEAR



The method of transportation by moving platform shown above can carry, according to the Public Service Commission, 72,500 people per hour at 12 miles per hour. Up to distances of 4 miles this is as fast as travel by the present combined express and local service. The express trains can carry 36,000 and the local trains 22,500 per hour. The successive platforms move at 3, 6, 9, and 12 miles per hour.

RAPID TRANSIT BY BELT CONVEYOR.—[See page 257.]

NEW YORK, SATURDAY, MARCH 26th, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## THE PRESERVATION OF THE CITY HALL PARK.

IT is a positive misfortune that the lack of a co-ordinated plan, coupled with the astounding rapidity with which the city has been built up, to say nothing of a total want of foresight on the part of the municipal authorities, should have robbed the metropolis of the New World of the opportunity to present those aggregations of magnificent municipal buildings, grouped about spacious and carefully laid-out plazas and public squares, which are one of the glories of the great cities of the Old World. Such public spaces as we possess have been gradually encroached upon, and their intended vistas have been closed, and too often positively disfigured, by buildings of no architectural beauty, which have been run up apparently without any appreciation, and certainly with a total disregard, of the architectural opportunities thus presented and so ruthlessly thrown away.

Perhaps the best known of our public squares is City Hall Park, which, early in the last century, was beautified by the erection of that gem of municipal architecture, the City Hall, a building which even at this late day maintains its position unchallenged as the most perfect piece of work of its kind in New York, if not in the whole of the United States. For the greater part of a century this classic building was practically the sole occupant of the park, and, standing in the midst of its green lawns and surrounded, though not obscured, by an adequate growth of timber, this beautiful structure long remained as the dominating feature of what is certainly the most interesting and in some respects the most beautiful of our smaller city parks.

The first desecration of this spot occurred when the Federal government erected at the apex of the triangle that unsightly pile which for several decades has done duty as the General Post Office, a building which not only entirely shuts out the charming view of City Hall and the Park which was formerly obtainable from Broadway, but constitutes in itself a monument to the total lack of refinement which marked the public architecture of the day in which it was built.

And now it is proposed not only to further encroach upon the already restricted area of the park by building thereon a County Court House of colossal dimensions, but it is intended, if you please, to place this structure immediately behind the City Hall, whose just proportions and delicate beauty will be entirely dwarfed and ruined by the towering and widely overlapping façade of the building. Although it may be a palliation, it is certainly not a justification of Mayor Gaynor and the other city officials who favor this course, to state that they do so unwillingly and after a sincere endeavor to secure some other suitable site. For there is a possible, though very costly, escape from the dilemma by means of the alternative plan which originated with the architects of this city and is receiving the indorsement of the leading artistic, municipal improvement, and historical societies, to say nothing of a thoroughly unanimous public press. This proposal is that the city purchase the two blocks lying immediately to the north of the City Hall, and place the new Court House upon the land so secured, the various departments being housed in the large office and other buildings now covering this land until such time as the new Court House is ready for occupancy. As the needs of the city demand it and the funds become available, the land so acquired would be covered with other municipal buildings of a monumental character, and ultimately this group of buildings, and the City Hall Park with the present historic structure, would form an important center with landscape and architectural effects of dignity and beauty that would be commensurate with the importance of a city which is destined ultimately to become in size, wealth, and importance the leading city of the world.

In giving our hearty indorsement to this proposal, we are not unmindful of the fact that New York city has now in contemplation public works on an enormous scale involving the expenditure of vast sums of money. But we also realize that in municipal as in other affairs, conditions may occasionally arise in which sacrifice on the part of the present generation, large as it may appear at the time, may come to be regarded by posterity as but a small price to pay for the lasting benefits conferred.

The present crisis surely presents an opportunity of this very character.

## THE MEYER NAVAL REORGANIZATION TO HAVE A FAIR TRIAL.

IN view of the diversity of opinion which was developed at the hearing of the House Naval Committee, that body followed, we think, the wisest course in failing to recommend any legislative action until Secretary Meyer's plan has been in operation for a sufficient length of time to prove the extent of its practical utility. As to the wisdom of some of the changes which the Secretary has made, there can be no possible difference of opinion. The institution of a separate and independent Bureau of Accounting is one of the best reforms that have been introduced into the navy for many a decade, and already at the Boston yard, where it has been for a considerable time in operation, the system has shown very satisfactory results.

We are also heartily in sympathy with the proposal of the Secretary to dispose by sale of those of our older vessels, which are so deficient in certain necessary qualifications of a modern warship as to render the expenditure of a heavy sum of money upon them for repairs and reconstruction a very doubtful policy. A few years ago England struck off the list and put up at auction over one hundred of her warships, and there is no question that her navy was the better for this very drastic pruning out of dead and decayed material.

Although the proposal to separate the work of the navy yard under the broad division of hull and material is based upon logical grounds, and would ultimately prove to have working advantages of a practical character, we think that the proposal to so separate the work is somewhat premature, and this for the reason that we have not to-day among the engineering corps a body of men of sufficient shop experience to qualify them for that oversight of the shops which is contemplated in Secretary Meyer's plan. If the institution of a separate department of machinery includes as an indispensable corollary the training of a certain number of the naval engineers for *permanent shore duty* as managers of the steam engineering shops of the navy yard, the success of the plan would seem more certain. In any case, we believe that until such a trained body is available it would be advisable to continue both the steam engineering and construction shops under the management of the naval constructors.

Now that the Meyer plan is assured of a lengthy period of trial, the country may rest assured that the whole of the naval service affected by the changes will co-operate in a loyal endeavor to give the new plan such a perfectly fair trial as will serve to determine its practical utility. Therefore we greatly regret to see that a prominent New York daily paper has so far forgotten the dignity which attaches to its well deserved reputation, as to indulge in a bitter personal attack on certain naval officers who have recently testified before the House Naval Committee, and that our contemporary has gone so far as to insinuate that because some of these officers were not in sympathy with certain features of Mr. Meyer's plan the only proper course left for them to pursue was to tender their resignations.

It is unjust and misleading for that journal to omit to state that these officers had no choice in the matter of giving testimony before the House Naval Committee, when once they had been summoned before that body, and that it was the wish of the Secretary that they should reply to the questions of the committee unhampered by any consideration of whether their views were or were not in harmony with his own.

So far from their frank expressions of disagreement with certain phases of the Secretary's plan showing in any sense a spirit of insubordination, we rather take it to be evidence of a true moral courage which places the highest interests of the navy above any consideration of a purely personal character.

Therefore to insinuate, as does the New York Sun, that from these and other gentlemen in the navy who may happen to disagree with certain parts of the Secretary's plan, it would be impossible to secure proper co-operation during the coming months of trial, is to betray a complete ignorance of that high professional spirit which pervades the United States Naval Service, and is nowhere more conspicuous than in that hard working and little appreciated body of officers, the Naval Constructors.

## THE SCOTTISH SHIP CANAL.

THE British government having reviewed the various projects for a ship canal through Scotland, whereby the Forth and the Clyde can be connected, have decided that so far as naval requirements are concerned, the most favorable route is that through Lochs Lomond and Long, or as it is generally called, the "Low Level Route." Such a canal the government states would unquestionably possess some strategical value, and as they would financially assist such a scheme, the promoters of the enterprise are urged to push the matter forward in commercial interests. The government, however, stipulates that the canal shall have a floor width of 148 feet, a depth of water of 36 feet, and locks 850 feet long by 110 feet wide at the entrance, with a depth on the sill of 36 feet.

A sea level canal was found to be impossible, for although the mean level of the sea is practically the same on the Clyde and the Forth, the level at high water is not, so that a sea level canal would produce sharp tidal currents which would involve serious risks in navigation.

According to the designs which have already been prepared, the entrance to the canal from the North Sea would be a little distance north of Grangemouth, striking inland in a northwesterly direction, skirting Stirling on the south and running into the Forth valley, which does not attain a higher elevation than 30 to 60 feet above sea level, then passing through the haunch of Ben Lomond into the valley of Endrick. This cut would be the heaviest on the whole route, the ridge attaining a maximum height of 260 feet above sea level. But it is short. Entering Loch Lomond, the waters of which are deep enough for the largest vessels afloat, the loch is followed for 13 miles to Tarbet, where another cut is made through the neck of land, 1¾ miles wide, separating Loch Lomond from Loch Long. The latter would be entered at Arrochar and this loch, which has a very great depth of water, is followed until the Firth of Clyde is reached opposite the Cloch Lighthouse. The locks would be placed at either end of the canal, that on the Clyde to lift the vessel to the level of the water in Loch Lomond, which is 22 feet above the mean level of the sea, and the other at Arrochar to regain the sea level in Loch Long.

The total length of such a canal would be 51 nautical miles, of which 30 miles would be in canal and the other 21 miles in the open waters of Loch Lomond and Loch Long. The deepest cuts would be one of 191 feet near Stirling, another of 285 feet at the head of the Forth valley, and one of 142 feet between Tarbet and Arrochar. These cuts though deep are very short. The vessels will have to be lifted at the Forth end of the canal 13 feet at high water and 31 feet at low water; at Arrochar the lift would be 17 and 27 feet respectively. In addition a regulating lock would be formed at the head of the Endrick valley to be used when Loch Lomond is in high flood.

Further advantages of this route are the avoidance of river deviations, only comparatively small brooks being encountered, which could be easily syphoned across the canal. Only one deviation would be necessary, that of the Endrick, which after all is only a stream. Again, the minimum of interference with the railroads will be offered. No swing bridges will be necessary and it will be possible for vessels to proceed without shortening their masts. The sharpest curve will have a radius of two miles. The construction of the canal will entail the excavation of 170,000,000 cubic yards of material, and its cost, to meet the Admiralty requirements, would approximate $120,000,000. Work would occupy seven years.

Apart from its strategical value, the canal would have distinct attractions for commercial traffic. It will offer a shorter route between America and Europe, and will avoid the dangerous passage *via* the Pentland Firth. The extent of this "North About" traffic as it is called, including the coastal traffic, is considerable, and the saving of from 100 to 500 miles in the sea journey of the transatlantic vessels, according to the situation of the European port, would be an important consideration. The aggregate of this traffic which would use the canal is 10,724,805 tons per annum, and at an average rate of 37½ cents per ton this would yield an annual revenue of about $4,021,800, which after deducting $300,000 as the annual cost of maintenance, etc., would yield about 3 per cent. on the capital for an Admiralty canal. The scheme is being actively pushed forward, and so soon as some idea of what the government would be prepared to do financially is obtained, no difficulty will be experienced in securing the necessary financial support to construct the waterway.

## AERONAUTICS.

**M. Ader,** the Frenchman said to have flown about 1,000 feet in 1897 with his steam-propelled monoplane, the "Avion," has recently been decorated with the red ribbon of the Legion of Honor. His machine is said to have embodied the wing-warping principle since patented by the Wrights.

**Proceedings have** been begun in France to invalidate the Wright patent No. 342,188, of March 24, 1904, on the ground that the patent was not worked in France within three years, as must be done according to the statute. In searching for anticipations the French lawyers have discovered the English patent No. 392 of Mathew Watt Boulton, granted in 1868, which provides movable wing tips or "ailerons" for the purpose of transverse stability. In 1870 Richard Harte, another Englishman, took out a patent (No. 1469) for maintaining transverse stability by means of revolving wing tips operated by a weight.

**The second** annual combined aeronautic and motor boat show opened in Olympia, London (England) on March 11th. Besides numerous small models, forty to fifty aeroplanes and balloons were shown. In addition to the regular French models of Wright, Blériot, Farman and Santos Dumont, a number of British built duplicates were shown by well-known firms, as the Humber Company, for example. In addition to these there were a number of new aeroplanes built by English inventors. Interest in aviation is very strong in England at present, and several big aviation meets are planned for the coming summer.

**In preparing** for a re-hearing of his case on the 19th inst., Glenn Curtiss has experimented to see how much resistance can be interposed at the ends of the planes of his biplane without causing it to swerve. He used small vertical fins 1x2 feet in size, and found that these could be set at right angles to the line of flight for a few seconds without causing the aeroplane to swerve from a straight path and without moving the vertical rudder. As the resistance of the balancing planes which Curtiss uses is far less than is obtained in the manner just described, there can be no turning tendency produced by them, and hence no use of the vertical rudder in conjunction with them. Mr. Curtiss has also flown with the vertical rudder tied and with it loose, showing that a movement of this rudder is not required. We also learn that the Autoinette monoplane has been flown with the vertical rudder left off. With these practical demonstrations of flight without the use of the Wrights' patented combination, there seems to be little doubt that any infringement suits they may institute will be successfully defended.

**On Saturday** March 12th, Aviator Louis Paulhan made only a short straight line flight of 500 to 600 feet at the Jamaica race track. The strong wind of 25 miles an hour velocity, and the few spectators were the principal reasons. On Sunday, however, several thousand people journeyed to the track, many of them in automobiles, and despite a wind nearly as strong as that of the day before they were not disappointed. About 4:45 P. M. Paulhan started against the wind, which was blowing directly across the track. His machine rose after a run of some 75 feet and traveled diagonally across the track while ascending constantly at an angle of 15 to 20 degrees. It rose to a height of 300 feet above the trees on the opposite side of the track, then, turning around, it sped back with the wind, passed over the grand stand and, making a sharp turn, swooped suddenly to earth at the very point at which it started 8 minutes before. Paulhan's was the most thrilling exhibition of flight ever seen near New York, and it is unfortunate that a dispute with his manager has stopped any further demonstrations.

**On March** 1st and 2nd Mr. Henry Farman made some record flights with passengers with a new biplane. His machine was originally built for the Rheims meeting last August, but it did not fly then owing to an accident. Despite its small size and surface, it showed excellent lifting power and stability. The spread of the upper plane is 34 feet, while the lower plane is 12 or 14 feet shorter, besides having a large section cut away in the center to accommodate the propeller. Movable flaps are fitted to the back edges of extensions of the upper plane only, and the tail consists of but a single horizontal surface between the two halves of the vertical rudder. The machine is mounted upon combined runners and skids and fitted with a 50 H. P. Gnome revolving cylinder motor. On the 1st inst. Mr. Farman made a flight of over 16 minutes with Mme. Franck and another passenger, thus beating his three-person record of 10 39 made at Bethany on August 28th, 1909. The following day he again flew with two passengers and remained aloft 63 minutes, or more than four times as long as the day before. On account of its reduced surface, Farman's biplane must have lifted over 2 pounds per square foot, which is a high figure for a biplane.

## ELECTRICITY.

**In September** of last year the Boston and Maine Railroad established a telephone train dispatching system on the line between Boston and Fitchburg, Mass. This system proved so satisfactory that the railroad is now about to equip two new divisions with telephones. One of the divisions consists of a 95-mile line, from Concord to Woodsville, N. H., and the other of a 70-mile line, from Concord to White River Junction, Vt.

**In a lecture** before the Engineering Society at Birmingham, Sir Oliver Lodge discussed the question of protection from lightning. He stated that the problem consisted in finding the best method of dissipating the enormous energy of the flash, but that it was not wise to get rid of the energy too quickly. A thin iron wire is considered the best lightning conductor from the electrical point of view, but it is almost impossible to protect a building from lightning unless it is completely enveloped in a metal cage. It is by no means true that a building is safe when provided with a conductor reaching up to the tallest part of the building.

**Experiments made** with ultra violet light appear to show that it is more effective for sterilizing liquids than ozone. The ultra-violet light is produced by means of mercury vapor lamps, quartz tubes being used instead of glass tubes which are placed in direct contact with the water to be purified. A French investigator, M. Victor Henri, has found that the bactericidal action varies greatly with the distance of the lamp from the bacteria. With a Cooper Hewitt lamp of 110 volts an exposure of 300 seconds at a distance of 60 centimeters was required in order to kill the bacillus coli. At a distance of 40 centimeters an exposure of 180 seconds was sufficient, and at 20 centimeters 20 seconds. The temperature appeared to have little if any, effect for the microbes were destroyed even when the liquid which contained them was frozen. In treating opaque liquids such as milk it was necessary to spread the liquid out in a thin layer. For milk the maximum thickness of layer with which the effect could be produced was one inch. Another investigator produces the ultra violet light by means of electric discharges in a rarefied atmosphere of carbon monoxide, carbon dioxide, sulphureted hydrogen, or sulphurous acid.

**An interesting** description of the rural telephone lines in the Ozarks was published in a recent number of the Electrical Review and Western Electrician. Every farmer in this region, no matter how poor he is has a telephone. The telephone lines have been installed by amateurs and every variety of telephone is used on them. Owing to fear of lightning the connection from the pole line to the house wire is made by bending the ends of the wires and hooking them together. When a thunder storm approaches this connection is unhooked and it frequently happens that the owner forgets to re-establish connection with the main line after the storm. The lines are all grounded, making it very difficult for one party to call another. Fifty telephones to a line is considered a light load. The lines are supported on such poles as can be easily obtained, which are seldom sunk to a sufficient depth in the ground to prevent them from leaning at all angles. Trees are also used to support the lines and the branches are seldom cut away to clear the wires. However the subscribers appear to be satisfied if only their line "talks." The subscribers usually combine to put up a switchboard in the nearest town and pay some one for attending to the calls.

**A very** interesting method of electroplating has been developed in England. The metal that is to be deposited is mixed in powdered form with other substances and it is merely necessary to wet the powder and rub it on the surface that is to be plated. The other ingredients are an electro-positive metal, such as zinc or magnesium, an inert substance such as chalk, and a salt which when wet serves as an electrolyte. The following description of the process is given by the author: "The electro-positive metal constitutes the anode and the object treated the cathode, and as 'Galvanit' contains a quantity of finely powdered electro-positive metal it makes innumerable contacts with the cathode surface and acts as so many minute anodes. These innumerable minute anodes gradually dissolve, and in dissolving set up in the liquid little local circulations of electric current. The circuits are so excessively small, so exceedingly near together, and so numerous that they cannot be separately observed, and the surface of the metal becomes the seat of innumerable concomitant voltaic and electrolytic actions. Thus the potential or stored up energy of the elementary substances in the powder is converted into electric current, and as these currents leave the liquid they throw down from the metallic salt in solution a thick film on the cathode, and it becomes plated over with a deposit."

## SCIENCE.

**Prof. Lowell** announces that he has discovered a new canal a thousand miles in length on Mars. The canal developed between May and September last.

**It is stated** that many of the library newspapers, printed twenty years ago, are disintegrating because our modern wood pulp paper is not permanent.

**The collection** of Indian costumes, weapons and utensils brought together by E. W. Lenders of Philadelphia and valued at $30,000, has been bought by J. Pierpont Morgan and given to the American Museum of Natural History.

**The astronomical** clock at Hampton Court Palace has been removed for repair and repainting for the first time for nearly thirty years. The clock, which was the first of its kind in England was made for Henry VIII in 1540. In 1880 it was brought from a shed at the palace where it had lain for nearly half a century, and by order of the Office of Works was re-erected in the position which it has since occupied in the courtyard of the palace.

**The comet** discovered by Daniel in December is not the same as one discovered in 1867, for which a period of about forty-two years had been found. Daniel's comet has been found to belong to the Jupiter family of comets having a period of about six and a half years. There are now over thirty of these and four or five of them pass through perihelion every year, but they are in many cases so faint as to elude observation altogether.

**W. W. Coblentz** has discovered that one of the ingredients of the milky fluid which the firefly (*Photinus pyralis*) exudes when touched exhibits an intense blue fluorescence when it is exposed to ultra violet rays. The fluorescence spectrum is very bright and continuous from 480$\mu\mu$ to 510$\mu\mu$. ($\mu\mu$, the unit in which wave lengths are measured equals 1/1 000,000 millimeter or 1/25 000 000 inch.) The "phosphorescent" light which the firefly emits at night is orange-colored and its spectrum extends from 510$\mu\mu$ to 670$\mu\mu$. Hence the two spectra are mutually complementary.

**In the northern** part of Archangel, which is the most northerly government of European Russia, a farm for the breeding of Kamschatka otters, blue foxes, sables, martens, and other valuable fur bearing animals is being established by German capitalists. The soil and climate of this district are exactly suited to the animals and the annual rental charge is only about 5 cents per acre, so that the venture appears very promising at first glance. On the other hand a large initial outlay is required. The farm contains 1 200 acres, is inclosed by a fence covered with sheet iron which has cost $67 000, but the burrowing propensities of the foxes and rodents will probably make it necessary to extend this barrier underground, at a large additional expense.

**F. Soddy** finds that the growth of radium proceeds according to the square of the time. On the assumption that no other intermediate bodies intervene the period of the direct parent of radium is 17 500 years. The amount of radium present in the last prepared solution is less than that to be expected, this suggests the existence of at least one new product, "Uranium A" intermediate between uranium X and the parent of radium with a period of the order of one year. It is concluded that this would not appreciably alter the production of radium according to the square of the time over the period observations have been made, but it would vitiate the calculations of the period of the average life of the parent of radium according to the Rutherford formula.

**A German** bird fancier has made a series of experiments for the purpose of determining the vitality of eggs in different stages of incubation. On the fifth day of incubation five canary bird's eggs were taken from the nest, marked with numbers and replaced in the nest, one by one at half hour intervals. This experiment was repeated ten times with as many clutches of eggs. As a rule the first three eggs replaced hatched normally and the two others failed to hatch. Hence it may be inferred that the average longevity of a canary bird's eggs taken from the nest on the fifth day of incubation is 1½ hours. In the same way the longevity was found to increase to 2 or 2¼ hours on the seventh day and 3½ to 4 hours on the ninth day of incubation. It was discovered by accident that eggs in a very advanced stage of incubation can endure very much longer periods of removal from the nest. Two eggs, purchased as plover's eggs, in the course of an excursion, were stowed in a basket, brought home and forgotten. On the evening of the following day a faint "peep" recalled the existence of the eggs and it was found that a young snipe had issued from one of them. The second snipe soon made its appearance but lived only an hour. Hence it appears that the vitality of partly hatched eggs depends on the size of the bird as well as on the stage of incubation.

# An Account of a Trip in the Largest Balloon Ever Constructed

## A BALLOON TRIP OF FORTY YEARS AGO.

It is doubtful whether the sensation of traveling in an airship has ever been better described than was done forty-nine years ago last June by Garrick Mallory and published in the Philadelphia Inquirer, June 30th 1860 after a voyage in the largest airship that had ever been constructed up to that time

Mr Mallory was a gentleman of education and fine descriptive talent and later commanded a brigade of cavalry during the civil war Prof T S C Lowe, the aeronaut in charge has a distinguished civil war record as an aerial scout He is constructing a great modern airship in his home city, Pasadena, Cal Here is Mallory's account, somewhat abbreviated

"The ascent of Mr Lowe's mammoth airship on Thursday last was by no means an ordinary occasion *Soi-disant* scientific aeronauts had in treatises and speeches positively demonstrated that it could not float Accordingly, when on the ground, we were beset with gratuitous advice from self constituted professors and atmospheric voyagers to the effect that it was madness to risk the untried experiment, and as to our friends we were ridiculed, threatened, cajoled, bribed, and wept over by turns

"So we held a council of war with ourselves in attempted cool reason and positively could not see why an increase of capacity in a balloon must necessarily diminish its efficiency, or that a greater range in the amount of gas to be evolved on the occasion, and in the number of sand bags to be retained or thrown away according to the object of ascent or descent, should destroy control over the element to be navigated

"The few uncut ropes are held by strong arms, the enterprising workman who seems to desire an ascent on the edge of the basket is induced to get down and put a bag of sand in his place, the other two gentlemen who determine at the eleventh hour to acquire aerial honors scramble in when the swaying has begun, the 'last dying speech and confession' has been made, all hands let go—and we are off! We don't believe it, however, in the slightest degree There is no motion perceptible, and we ourselves are entirely stationary Something to be sure is the matter with the field It has dropped Perhaps that is the reason why the crowd down below there is making such a noise They

LOWE'S DIRIGIBLE BALLOON.
After an old newspaper print.

are frightened, most probably To be sure, they have some reason, for it is a rather alarming occurrence for the solid earth to fall down in that way, especially when all nature is so calm, and the sun shines so happily, and our car is so nice and fixed So we feel badly about our unfortunate fellow beings who are momentarily becoming smaller Suddenly a brilliant idea seizes us that we have actually begun the great ascent, and we forthwith begin to wave the flags and hurrah and jump No, we don't jump, for there isn't room, but we would if we could. The mites down below give cheer after cheer responsive, and run futilely in our course, and we fly away

"Although nothing could have been easier than to have risen immediately to a great height, yet as the lower breeze was northerly and light, we purposely remained in it, as thereby a deliberate view of the city and its environs was presented that could not be hoped for once in a thousand times. We had precisely the day, the hour, the current, and, above all, the balloon for a bird's eye inspection of Philadelphia, so sailed calmly on, silent, and ravished with ecstasy At the altitude of three thousand feet we look down fondly on Gray's Ferry, Darby, and the park, scenes of our equestrian pleasures, and then turn to the sparse houses of semi rural Moyamensing, picturesquely isleted in green lakes and foliage Next we glide on over the great city, seeming to lie asleep in that soft summer evening, with never a breath to disturb its happy rest, save the vague murmur of life which steals upward toward us, like the distant hum of invisible insects. We are higher now, and to the naked eye vast buildings like the Continental are distinguished chiefly by their known position, but as we pass along, the streets radiate on all sides with mathematical exactness, bordered with faint green lines of foliage. The public squares are patches of verdant enamel, and the spires point up at us with the beams of the sun shining from their whiteness until they only can be likened to the hoar-frost appearing on a window in winter Far away Girard College is discerned in the distance as an anthill of marble dust, and Fairmount is found in a fairy toadstool, with the Schuylkill curving close to it like a silver thread dropped, perhaps, from the robes of Titania herself But it is perfectly in vain to attempt any description of this most exquisite scene, which naught but the colors of the most gifted could pretend to convey to any who have not beheld it Indeed, it was all to us but a seeming picture seen in an enraptured vision There was no reality about it We were real, and the car, but every-

# VERTICAL PHOTOGRAPHY

## BY CHARLES MONROE MANSFIELD

In recording scientific material, whether plants or their fruits, or any peculiar material of which a record in picture is valuable, the exact size is always desirable Various apparatus have been constructed to support the camera and hold the subjects, but the real secret lies in the focus of the lens Any subject placed twice the focal length of the lens from the lens, and the lens twice its focal length from the focal plane, will give a picture natural in size For example, a nine-inch focus lens placed eighteen inches from the subject and the focal plane the same distance from the lens will give a natural size image in focus on the ground glass without further adjusting the camera

Nearly all actual size work is done vertically This gives the operator the privilege of manipulating his 'under ground during the exposure without interfering with the subject. The object to be photographed is usually placed on a glass support, which may be either plain or ground, and the back or under

(*Concluded on page 267*)

Just an ordinary camera and tilting tripod top. The legs of the tripod may be adjusted to give the camera the needed height. The glass may be supported by four corks or a wooden frame as shown in the photograph

The operator can revolve the entire outfit during the exposure. This gives uniform lighting and illuminates the shadows. This camera may be suspended from a tree.

This is a very simple stand for vertical photography. The camera may be moved up or down the groove in the stand and the glass frame can be regulated to any height by a worm screw on the back. This stand was made by a photographer at a very small cost.

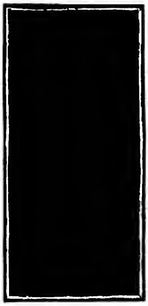
The tripod supports are so arranged that the camera may be set up vertically The ground glass object support is regulated by a thumb screw on the camera bed, and the bellows racked back and forth at the will of the operator. This is the same camera that is suspended from the chain.

VERTICAL PHOTOGRAPHY.

# AN INTERNAL COMBUSTION WATER PUMP

## THE INGENIOUS INVENTION OF H. A. HUMPHREY

Widespread interest has been aroused in European engineering circles in a new type of pump that has been evolved by a well-known English engineer, Mr H. A. Humphrey, M. Inst, C. E. It is based upon an entirely new principle, and is a revolutionary departure from existing practice, the novelty of the design compelling as much attention as its remarkable efficiency and economy



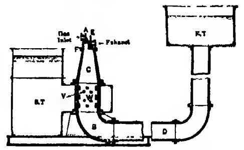
INTERNAL COMBUSTION WATER PUMP.

The pump is based on the fundamental principle of internal explosion, but does away with all the usual working parts of a gas engine, such as the piston, connecting rod, crankshaft, fly wheel, two-to-one gear cams and bearings There are no moving parts whatever except the simple mushroom valves, which open and close automatically, due to pressure changes, and the use of a flywheel is not necessary because a column of water, forming part of the water pumped, acts as a reciprocating flywheel. The water column, which also acts as a piston, has four unequal strokes, such as theory requires when expansion is carried to atmospheric pressure. These strokes comprise long strokes during combustion and expansion as well as during exhaust, a shorter stroke during suction, and a still shorter stroke during compression There is no valve across the discharge pipe at any point, so that the water has a perfectly free passage from the explosion chamber to the high level tank.

The explosive mixture of gas and air is ignited, as in the ordinary internal-combustion engine, and in contact with one end of a column of water which fulfils the dual function of piston and flywheel and moves so as to draw in a fresh combustible charge, to compress this charge previous to explosion, to permit expansion to be carried to atmospheric pressure, and finally to exhaust the products of combustion. All these movements are brought about and controlled by changes in the momentum, which occur naturally in the column of water itself

In order to explain the cycle of operations in a pump o the simplest type, a reference to the accompanying diagram will be found useful. The pump proper is built up from three main castings. There is the combustion chamber C, the water valve chamber W, and the bend B, which connects the pump to the discharge pipe D, leading to the elevated tank E T The suction tank S T is extended to embrace the valve-box chamber, as shown, so that there is free access of water to all the water valves V The last are plain mushroom valves, opening inward, and held on their seating by light springs In the top of the combustion chamber is an inlet valve A, as well as an exhaust valve E Arranged between these two valves is a simple interlocking device, so that when valve A has opened and closed it locks itself shut, and releases valve E, and when valve E has opened and closed it locks itself shut and releases valve A Consequently, each time suction occurs in the chamber these valves open in turn.

For the purpose of demonstration, suppose a gaseous charge is compressed in the top of the combustion chamber C, and is ignited in the usual manner by the sparking plug, which projects through the top casting or head of the combustion chamber All the valves are shut at the instant the charge is exploded, and



SECTIONAL VIEW OF INTERNAL COMBUSTION PUMP.

the increase in pressure resulting from the expanded gases forces the water downward in the pump, and sets the whole column of water in the bend B and discharge pipe D in motion The column of water attains kinetic energy while work is being done upon it by the expanding gases, so that when those gases finally expand to atmospheric pressure, the column of water may be moving, say, 6 feet per second The motion

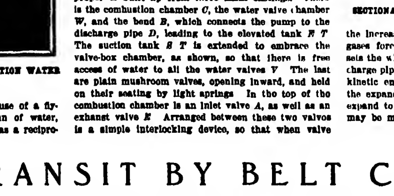
# RAPID TRANSIT BY BELT CONVEYOR

## A PROPOSED AMPLIFICATION OF NEW YORK'S SUBWAY

The method of rapid transit by means of continuously moving endless platforms has never as yet received the attention which its unquestionable advantages deserve, for, within certain limits of speed, it possesses a capacity for carrying passengers which is so far beyond that of any existing system as to place it in a class by itself That the system has not been put into practical application in the solution of those problems of congested city traffic for which it is so admirably adapted, can only be explained by the extreme novelty of the method employed, the inertia of that deep-rooted conservatism, which, even in this strictly utilitarian age, exerts such a powerful controlling influence on human affairs. The construction and operation of the moving passenger platform is so simple, and its great carrying capacity is so obvious, that its advantages are readily perceived even by the layman who may have no particular mechanical aptitude or training, and it is certainly significant that the proposal to equip a section of the proposed New York Subway with a moving platform has received the indorsement of such men as Henry B. Seaman, the Chief Engineer of the Public Service Commission, and of Mr. L. B. Stillwell, the electrical engineer who was responsible for the electrical equipment of the Elevated Railroads and the New York Subway system. Interest in the proposed moving platform has been recently revived by the recommendation of the Board of Estimate of this city that a moving platform be installed in a subway extending across Manhattan Island from the East to the Hudson River below Thirty-fourth Street, and on the front page of the present issue is a sectional illustration, which shows the general character of the construction both of the subway and of the moving platform itself.

In those branches of our industries, for the economical operation of which it is absolutely necessary that material be conveyed from place to place at a maximum speed and with a minimum cost, it has been found that there is no system of transportation which so perfectly fulfils these conditions as the belt conveyor Particularly is this true where a great bulk of material, consisting of more or less finely divided units, such as coal, iron ore, and wheat, have to be moved in great quantities with as little interruption as possible and without any manipulation by hand In this system, an endless belt moves continuously in a given direction, and facilities are provided for loading the material on the belt at any desired point and for unloading it therefrom at any desired point of delivery

The moving platform is nothing more nor less than a huge belt conveyor, in which the material to be conveyed consists of the teeming millions which constitute the passenger traffic of a great city, with provision for loading the passengers at any point throughout the length of the platform and unloading them while the latter is in motion The train consists of short jointed platforms, coupled together and forming an endless chain which is kept in continuous motion This platform is provided with transverse



View of the method of driving the platforms by means of stationary electric motors and differential rubber-tired wheels.

RAPID TRANSIT BY BELT CONVEYOR.

seats, and it travels at a continuous uniform speed of twelve miles per hour For transferring the passenger from the fixed station platforms to the seated platforms, there are introduced between them three narrow "loading platforms" which move at differential speeds. The first of these adjoining the station platform moves at three miles per hour, the next at six, and the next at nine miles per hour The passenger who wishes to board the train, faces the direction in which it is moving, steps onto the three-mile-per-hour platform, and, crossing the other two successively, takes his seat. The success of the escalator or moving stairway, of which many are now in operation throughout the country, removes any doubt of passengers being able after a little practice to accommodate themselves to the speed of three miles an hour involved in boarding the train

The advantages of the arrangement as summed up by the Chief Engineer of the Public Service Commission are as follows

1 A vastly increased capacity, and seats for all passengers.

2 There is no delay incurred by waiting for trains at stations, as the train is always there and constantly moving

3 Passengers may board or leave the train at any point at will, and instead of placing stations one-third of a mile apart, as on the present Subway, they may be placed at every cross street, or indeed at any intermediate point, and the construction may take the form of a continuous arcade

In its general construction the tunnel would be similar to those built for the ordinary Subway traffic It is proposed, however, to build arcades throughout its length, with store windows at basement level, and continuous promenades between them and the barrier separating them from the Subway platforms At each street crossing, and if it be desired at one or more points between them ticket booths and turnstiles will be installed —an arrangement which would permit passengers to board the cars practically at any desired point throughout the length of the subway

The arrangements for driving the platform by electrical power are as follows Extending longitudinally beneath each platform is a pair of I-beams, the upper flanges of which are riveted to the bottom of the platform, while the lower flanges serve to support the weight of the platform upon pairs of wheels, which are carried upon transverse shafts mounted at intervals of 2 feet 9 inches, upon concrete piers, as shown in the engraving Between each pair of longitudinal I beams is carried a pair of horizontal guide wheels which engage a guide rail that serves to keep the platform in proper alignment At every 75 feet, 10-horse-power motors are mounted on the floor of the subway, and are connected by a chain drive

(Concluded on page 268.)

### CONDENSED FACTS ABOUT HALLEY'S COMET.

BY H. W. [illegible]

A few facts presented in a condensed form may possibly interest the readers of the SCIENTIFIC AMERICAN who wish to follow the course of Halley's comet in the heavens during its present appearance.

The last perihelion passage occurred on November 15th 1835. The present perihelion passage will occur on April 20th 1910. The perihelion distance will be 0.587, and the aphelion distance will be 35.10. The eccentricity is 0.967, the longitude of ascending node is 57 deg 16 min, the node and apsis angle is 111 deg 17 min, the inclination of the orbit is (162 deg 12 min +) 17 deg 48 min —, the longitude of perihelion is 305 deg + and the motion is retrograde, in other words opposite to that of the planet. The diameter of the nucleus cannot of course be stated with anything like accuracy at the present time, but it is not likely to exceed 120,000 miles.

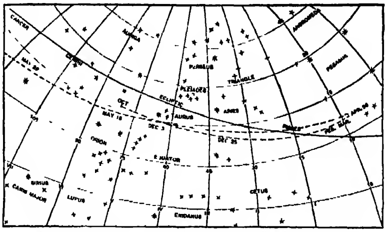
At the end of February Prof. Barnard of Yerkes Observatory estimated the tail to be 14,000,000 miles long. Just before and after perihelion passage the tail will be at least that long and probably longer. The comet is fast approaching its perihelion point, or point nearest the sun where, as we have said it is due to arrive on April 20th. During the months of February and March, the earth and the comet are racing on practically parallel orbits, 170,000,000 miles apart on opposite sides of the sun.

The comet first crossed the earth's orbit about March 10th at a point where the earth will arrive at the middle of next October, but far above where the earth will be so to speak for it will be some 10,000,000 miles above the plane of the ecliptic. In April the comet will emerge from behind the sun, and will become visible to the naked eye in the eastern sky before sunrise.

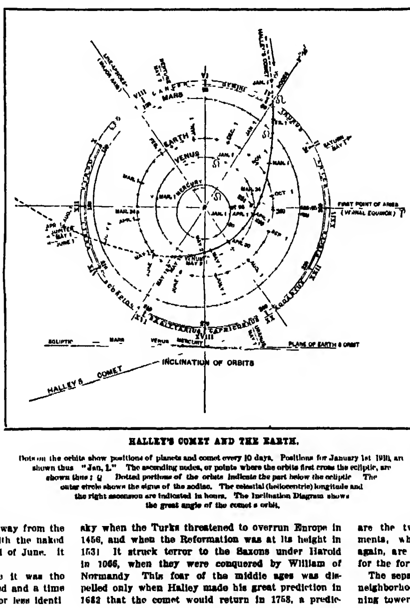
On April 20th, when the comet will swing around the sun, it will be 57,000,000 miles away from the sun. Its velocity will be 26 miles a second. The earth travels at about 19 miles a second. On May 2nd the comet will traverse the orbit of Venus, some 6,000,000 miles above the planet. In other words, an astronomer on Venus would find the comet a far more impressive spectacle than a terrestrial astronomer. As it rushes on, Halley's comet will pass between the earth and sun close to its ascending node. On May 18th the earth will be about 13,000,000 miles away from the nucleus or head as against 5,000,000 miles in 1835. Moreover, on May 18th the earth will be enveloped in the comet's tail for a few hours. A few days later the comet will be visible in the western sky after sunset with a 15 deg or 20 deg splendor. After that it will speed away from the solar system. The last glimpse of it with the naked eye will be obtained probably at the end of June. It will not reappear for seventy-five years.

Halley's comet is noteworthy because it was the first comet for which an orbit was plotted and a time table calculated. It has a history more or less identified with the history of human thought and civilization. The superstitious dread with which it was regarded in mediæval and ancient times swayed many a monarch. It was instrumental in forming the policies of Louis le Debonnaire in 837. It blazed in the sky when the Turks threatened to overrun Europe in 1456, and when the Reformation was at its height in 1531. It struck terror to the Saxons under Harold in 1066, when they were conquered by William of Normandy. This fear of the middle ages was dispelled only when Halley made his great prediction in 1682 that the comet would return in 1758, a prediction which was verified after the great astronomer was in his grave.

A comet which has reappeared regularly for over two thousand years must be composed of fairly enduring stuff. Just what its composition may be, the present reappearance will for the first time enable us to tell, for in 1835 the spectroscope was not invented, nor astronomical photography perfected.



THE APPARENT PATH OF HALLEY'S COMET THROUGH THE HEAVENS.



HALLEY'S COMET AND THE EARTH.

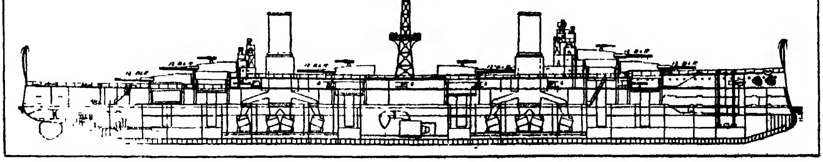
Dots on the orbits show positions of planets and comet every 10 days. Positions for January 1st 1910, are shown thus "Jan. 1." The ascending nodes, or points where the orbits first cross the ecliptic, are shown thus: ☊ Dotted portions of the orbits indicate the part below the ecliptic. The outer circle shows the signs of the zodiac. The celestial (heliocentric) longitude and the right ascension are indicated in hours. The Inclination Diagram shows the great angle of the comet's orbit.

### THE NEW ARGENTINE DREADNOUGHTS.

Thanks to two contemporaries devoted to South American interests, La Argentina and The Standard of Buenos Ayres, we are in a position to publish some quite complete information regarding the two new dreadnoughts, contracts for which have recently been secured by the Fore River Company. Comparison will naturally be instituted between them and our latest dreadnoughts, the "Wyoming" and "Oklahoma." They are 50 feet longer, have about 3 feet more beam, about a foot less draft, and their displacement is 1,500 tons greater. The ships are as fully protected, and if expectations are fulfilled, they will have two knots greater speed, a result to which their greater length and finer lines will largely contribute. The armor plan appears to be about the same, with the addition, however, of a certain amount of special protection against under-water attack. Because of the emplacement of the two central turrets diagonally, the end-on fire, both fore and aft, will be double that of our ships, the broadside fire will be about the same.

A study of the inboard profile for which we are indebted to La Argentina, reveals a symmetrical disposition both of the gun and motive-power weights, and one is impressed with the fact that, with the exception of the aftermost pair of guns, the battery is carried high above the water upon a lofty unbroken spar deck extending some 450 feet throughout the length of the ship. Another excellent feature is that the secondary battery is mounted entirely upon the main deck, or one deck higher than in our own "Wyoming." Hence, these guns should be capable of service in practically any weather in which an action could be carried on. The main battery is mounted in two stepped turrets forward and a similar pair aft and in the two turrets placed *en échelon* amidships. The single military mast, built apparently of open steel trusswork, is placed exactly at the center of the ship, and below it are the engine-room compartments containing the propelling turbines. Immediately fore and aft of the engine room are the turret hoists and ammunition rooms for the central pair of turrets. Fore and aft of these are the two separate sets of boiler-room compartments, while fore and aft of these compartments, again, are the turret hoists and ammunition rooms for the forward and after pairs of turrets.

The separation of the one military mast from the neighborhood of the forward smokestack, bridges, conning tower and forward turrets is advantageous, in-



Length, 604 feet. Beam, 98 feet. Displacement, 27,500 tons. Belt and Turret Armor, 12 inches. Armament: Twelve 12-inch, twelve 6-inch and twelve 4-inch guns. Speed, 22.5 knots.

SECTIONAL VIEW, SHOWING LEADING FEATURES OF THE TWO ARGENTINE DREADNOUGHTS.

| | Argentine Dreadnought. | U. S. S. "Wyoming." |
|---|---|---|
| Length | 604 feet | 554 feet |
| Beam | 98 feet | 93 feet 2½ inches |
| Draft, normal | 27 feet 6 inches | 28 feet 6 inches |
| Displacement | 27,600 tons | 26,000 tons |
| Speed | 22½ knots | 20½ knots |
| Belt armor | 12 inches | 12 inches |
| Turret armor | 12 inches | 12 inches |
| Battery | Twelve 12-inch<br>Twelve 6-inch<br>Twelve 4-inch | Twelve 12-inch<br>Twenty-one 5-inch |
| Fire ahead | Eight 12-inch | Four 12-inch |
| Fire astern | Eight 12-inch | Four 12-inch |
| Fire broadside | Twelve 12-inch | Twelve 12-inch |

asmuch as it is thereby removed from the favorite aiming point of modern gunnery, which is a little forward of the base of the foremast

The position of the 6-inch battery, with a protection of 8 inches of armor below and 6 inches in front of it, must be considered very satisfactory, although the protection is not equal to the 9 inches afforded to the 5-inch battery on our latest ships. Excellent also is the protection of the smokestack to a height of 15 feet above the spar deck by a special steel plate 1½ inch in thickness.

The following particulars taken from The Standard of Buenos Ayres, will be of interest The main armor belt will extend for 250 feet in the center, and 4 feet 9 inches above and 3 feet 4 inches under the normal water line, the uniform thickness being 12 inches The armored band will extend 75 feet toward poop and bow to the barbettes, but with the thickness of 10 inches only Above the principal belt of armor for the whole length of 400 feet there will be armor of 9 inches in the lower part and 8 inches in the upper part to the height of the main deck The bow and poop will also be protected by armor of 6 and 4 inches respectively On the main deck there will be a casemate with armor of 6 inches, in which the 6 inch guns will be placed The bases of the chimneys will be protected to 15 feet from the deck with a special steel plate 1½ inch thick The total weight of the armor, barbettes, turrets etc will be 7,000 tons The bottom of the ship will be protected against submarine mines with 660 tons of nickel steel The turbine engines will be in three separate and independent compartments, and the boilers will be in six compartments, divided into two groups The capacity of the coal bunkers is 4,000 tons and there will be tanks for 660 tons of petroleum The turbines will develop 39 500 horse-power with 25 millimeters of pressure of air in the boilers This, with a displacement of 27 500 tons, will give a speed of 22½ miles an hour for eight successive hours With this speed the radius of action will be 3,600 miles, at a speed of 15 miles the radius will be 7,200 and with 11 miles an hour 10,100 miles. The cost of each ship will be $11,000,000

### THE SCIENTIFIC AMERICAN FLYING MACHINE TROPHY

CONDITIONS FOR 1910

The Scientific American Trophy for heavier-than-air flying machines was offered by the Scientific American for annual competition under the rules and regulations formulated and promulgated by the Aero Club of America in 1907

The first trial for this cup was held at Hammondsport, N Y, on July 4th 1908, by the Aerial Experiment Association of Hammondsport N Y The minimum distance to be covered was one kilometer (3,280 feet) The trophy for 1908 was won by Glenn H Curtiss in the "June Bug," he having made a flight of 5,090 feet This was the first official public flight for a record made in the United States

The trophy was also won for the year 1909 by Glenn H Curtiss, who on July 17th fulfilled the new conditions of the competition for that year by covering a minimum distance of 25 kilometers The actual distance covered was 25 002 miles in 52 minutes 30 seconds, which was considerably in excess of the minimum distance required

Both of these trials were made under the supervision of the Contest Committee of the Aero Club of America

In accordance with the deed of gift which provides that the conditions for each contest for this trophy shall be made progressive in their severity of test in conformity with the progress of aerial navigation, the conditions to be fulfilled by the next person entitled to have his name placed on the trophy shall be a flight of not less than 40 miles across country The contest for 1910 must be held within the United States.

RULES GOVERNING COMPETITIONS FOR THE SCIENTIFIC AMERICAN TROPHY FOR 1910

I The trophy is to be the property of the club and not of the members thereof, except in the event that any one person shall win the trophy three times, in which case it is to become his personal property

Should the trophy be won by the representative of some foreign club affiliated with the Aero Club of America through membership in the International Aeronautic Federation, it shall be held in the custody of such club, but it shall be subject to competition under the same terms and conditions as if it were still held by the Aero Club of America. Should the holding club, for any reason, be disbanded, the custody of the trophy shall revert to the Aero Club of America.

Should a contest or trial under the rules not be held within a year from the date on which a foreign competing machine shall have won the trophy, the foreign aero club having possession of the cup shall give up its custody of the same and shall return the cup to the Aero Club of America, in order that the competition or trial for that year may be held in the United States of America

The conditions under which the competitive tests and trials shall be made shall be determined by the Contest Committee of the Aero Club of America and such conditions shall be made progressive in their severity of test, as far as possible, in order to foster and develop the progress of the art of aerial navigation

II All heavier-than-air machines of any type whatever (aeroplanes helicopters, ornithopters, etc ) shall be entitled to compete for the trophy but all machines carrying a balloon or gas-containing envelope for purposes of support are excluded from the competition

III In order to compete for this prize the contestant should file with the Aero Club of America a formal entry, addressed to the club at its headquarters in New York, declaring his intention to compete for the trophy Whether the trial is to be made at

THE SCIENTIFIC AMERICAN FLYING MACHINE TROPHY.

a recognized aeroplane meeting or at a special trial, the contestant should indicate the date upon which he seeks to make a flight. He must also deposit the amount of the fare from New York to the place of trial, and return

A reasonable time must be allowed for the representative of the club to reach the place where the flight is to be held If the trial is to be made within 25 miles of New York city, the amount of the fare will be defrayed by the club In case the Contest Committee find that the place of trial is too far distant, and they are unable to arrange to have an official present, the contestant may be required to hold the trial at some convenient place mutually to be agreed upon

IV The person or committee having charge of the test or trial shall make careful measurements of the distance covered by the flight, and shall prepare a written report of the test or trial, which shall be delivered to the Contest Committee of the Aero Club of America, and in such report shall state fully whether in his opinion the machine can be handled with safety, and, as far as possible, he shall determine the speed attained during the flight. He shall also take into consideration the question of stability and ease of control, and he shall state in his report weather and wind conditions.

V The flights will be made in as calm weather as possible, but the contest committee or its representative will at its discretion order the flight to begin at any time it sees fit, provided the velocity of the wind does not exceed twenty miles an hour The machine may start by running on the ground or upon a track under its own power, but no special launching device will be permitted There is no requirement as to the height above the ground at which the machine must fly

VI Complete specifications of the competing machine, giving weight, supporting surface and power of engines together with a description of the best trial of the machine, shall be forwarded to the Contest Committee at or before the time of making entry for the contest.

VII The trophy shall be awarded for the year 1910 to the contestant making the longest cross-country flight during the year The distance covered must be at least 40 miles as the crow flies, or to a point 20 miles distant, returning to the point of departure

The trophy shall not be awarded unless formal entry for the same has been lodged by the *bona fide* owner of the machine with the Contest Committee of the Aero Club of America in accordance with the conditions elsewhere specified The name and record of the successful contestant shall be appropriately inscribed on the trophy

VIII All tests and trials shall be under the official supervision and direction of the Aero Club of America, and all questions that may arise in regard to such contest or trial shall be decided by the Contest Committee of said club, and its decision in all questions of dispute shall be final, and without right of appeal to a court of law or equity

IX In case the Contest Committee is unable to determine which machine has made the best performance during the year 1910 it shall arrange that a competition between such machines be held, and the machine making the best performance in such test shall be awarded the trophy for the year

X No trial or test for the year 1911 will be allowed until the rules governing the competition for that year have been promulgated

## Correspondence.

### MR RIEDERER'S PROBLEM.

To the Editor of the Scientific American

Referring to Mr Riederer's puzzle in the Scientific American dated February 19th, 1910 I take the liberty of submitting what I consider to be the most orderly

### The Current Supplement.

W P Draper's excellent consideration of the artificial silk industry is concluded in the current Supplement, No 1786 Attention has been again directed to the possibilities of radium as a curative agent by Sir William Ramsay and Sir Lauder Brunton For this reason an article on the subject in the current Supplement should be read with interest Lucien Fournier describes the freezing process which was employed in the construction of the Paris Subway The case of Wright versus Paulhan, and some extracts from affidavits and Judge Hand's decision in the case of the Farman and Blériot aeroplanes is concluded H. Thurn writes on airships, wireless telegraphy, and atmospheric electricity Most interesting is an article by T Kume on Japanese pearl culture, in which he considers the pearl historically in Japan, mentions the Oriental bivalves which produce the best pearls, and then describes in detail the method employed by Mikimoto for the artificial culture of pearls Some experiments on the expansion of air by heat are described. Automobilists will read with interest an article on a variable stroke gasoline motor Prof T J J See contributes a thoughtful paper on the origin of the lunar craters, in which he endeavors to show that these wonderful craters may be explained by the impact of some sort of projectiles W Nernst contributes an article on general and physical chemistry in the last forty years.

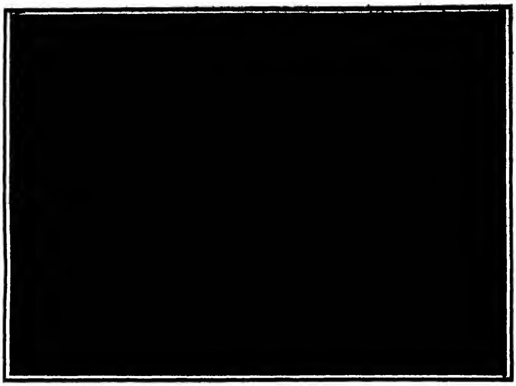
## A NEW TELEPHOTO CAMERA

BY THE PARIS CORRESPONDENT OF THE SCIENTIFIC AMERICAN

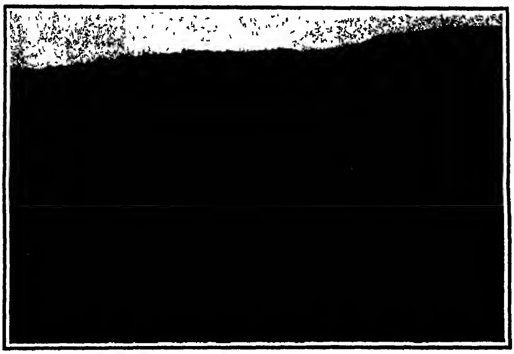
It may seem far easier than it is to construct a camera which will give an enlarged image so as to bring out the details of objects at great distances. To give a large image a long focus lens is required, of four foot focus for example. But a camera to use this lens must be of very great length and weight, and cannot, therefore, be said to be portable.

In the instrument illustrated which was designed on the Vautier-Dufour and Schä system, the inventors have solved the problem of preserving the focal length of the lens and at the same time reducing the volume and weight of the apparatus by cutting the focal length into thirds with the aid of two mirrors. At *O* is the lens which lies in the upper part of the double box. The rays passing through the lens are reflected from the upper mirror *M* placed at the back of the box to the mirror *M'* at the front end of the lower section, and thence to the usual ground glass *P* at the back. In this manner a camera of sixteen inches length is sufficient for a lens of four-foot focus, with an evident saving in weight and reduction of volume. Such an instrument is quite portable. The upper part of the camera is made on the extensible plan, and is drawn up and out of the lower box when the photograph is to be taken.

Up to the present time the different combinations of lenses for telephotography have all had one great fault namely, a want of luminosity and consequent difficulty in focusing. It was almost impossible to use such lenses for snap shots. The camera illustrated takes instantaneous views in the usual way. The

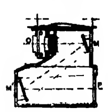


The city of Neuhausen and the Rhine Falls taken with an ordinary camera.



A photograph of military maneuvers taken with an ordinary camera.

lens opening is always in ratio with the focal length of the lens, *f* 10 to *f* 12 for the extra rapid. The luminosity is thus always sufficient for instantaneous work. For the photography of inaccessible places, such as mountains or details of architecture or scenes in which the interesting spot is at a great distance from the observer, the new camera performs very good work, as will be noticed in some of the engravings presented here. In a balloon the new system renders it possible to take rapid instantaneous views which would be impossible with an ordinary tele-objective. Such views are very difficult to take, not only because of the distance of the objects, but because of the continual movement of the balloon, which makes rapid snap-shots necessary. Snap-shots can now be taken up to 1-1,000th second which would be quite impossible with any tele-lens with which we are acquainted. At the full opening the present lens gives pictures which are sharp up to the edges of the plate.



O is the lens, the rays passing through the lens are reflected from the mirror M to the mirror M' and from there to the ground glass P. In this manner a camera of 16 inches in length suffices for a lens of 48 inches focus.

The present camera has already undergone trials in a free balloon on board the balloon "Mars" of the Swiss Aero Club, and the photographer took some very sharp views, which it would have been impossible to obtain with an ordinary apparatus.

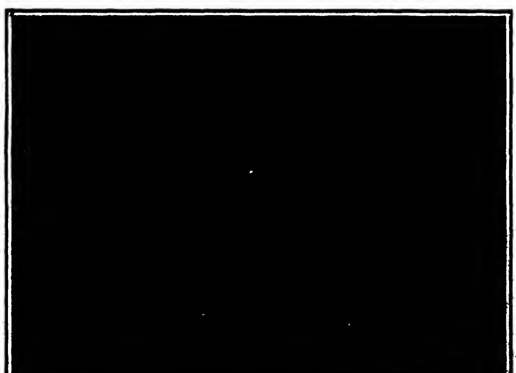
Its use in field work is shown in two of the annexed views representing army manouvers. In the first view, taken with an ordinary camera, the troops in the background can hardly be distinguished, while in the second view we clearly see the individual soldiers and can follow all their movements with ease. One of the views shows a photograph, taken on board the balloon "Mars," of the town of Neuhausen and the Rhine Falls at an altitude of 1,400 meters (4,620 feet) with an ordinary camera. The second view is taken from the same point with the new apparatus. Its use in architectural work is also seen.

## Why Are We Right-Handed?

BY JOHN R. RUSER, A.B., M.D.

From time to time ambidexterity is extolled as generally desirable, and there are to-day educators who consider that development of the left, coequal with that of the right hand should be begun with the entrance of little children in our schools. It is, therefore, perhaps profitable to discuss in what manner right handedness—by which I would here connote right-sidedness in general—has become habitual among 96 per cent of human kind; and whether ambidexterity is really desirable.

The lower animals, at least those which have not been taught tricks, use their fore paws indiscriminately, the cat strikes at a fly or plays with a mouse indifferently with either or both paws; the squirrel manipulates nuts and clings to branches quite as indifferently. Even in monkeys or gorillas, which of all animals use the fore paws mostly as hands, there is no suggestion of preferential use or superior expert-



The city of Neuhausen and the Rhine Falls taken with the Vautier-Dufour camera.

A NEW TELEPHOTO CAMERA

ness in the left or the right hand, states Dr. G. M Gould, but animals can be tutored to use one or the other paw, the dog is taught to shake hands with the right paw; the monkey to shoot manwise, with the musket butt at the right shoulder Among microcephalic idiots, whose small-headedness is due to arrested development, left-handedness and ambidexterity have been found to reach a proportion of fifty per cent. But as we go up in the evolutionary scale of normal creatures, and as we exclude disease, we find that ambidexterity progressively gives way to single-handedness—generally right-handedness Sir James Crichton Browne observed quite truly some years ago, that "by the superior skill of his right hand man hath gotten himself the victory" in the evolutionary struggle To try to undo his dextral pre-eminence is to make for devolution Glimpses of right-handedness in man, it seems, are manifest in the bronze age and in Paleolithic times It is evident in the art of the ancients—Assyrian Grecian, Egyptian Historic investigation shows that all peoples, however savage, have uniformly used by preference not only one but the same hand—the right. It is said that some races to-day manifest either handedness, but this is in the last degree doubtful Such statements have, for example, been made concerning the Japanese—that they are by law and practice ambidextrous. But Baron Komura has given positive assurance to the contrary Sir James believes it doubtful whether "strictly speaking, complete ambidextry exists in any fully developed and civilized human beings, though sometimes very close approximations to it occur"

Most human beings, then, are right-handed, though of course, there are those of great intellectuality and force who are ambidextrous having educated themselves to this end, and are exceptional by reason of the peculiar and special training they have undergone The origin of right handedness will be found, I believe, to lie much deeper than the individual's voluntary selection whether he will use his right hand or his left, or whether he will be ambidextrous, the reason is to be found in human anatomy—in the position of the heart, and in the cerebral structure and organization by which latter all voluntary movements are directed and controlled

Consider in the first place how the heart and its great arteries are left-sided, though in the primordial organism from which we have evolved there was, it seems, no such symmetry The savage, from time immemorial, has protected his heart with his left, his shield arm, but his aggressive manipulations are made with his right, his spear arm The modern savage too, though he bears no shield—which would be useless against modern weapons—fires his musket uniformly (in a double sense) from the right shoulder, sighting with his right eye, the sword also is wielded in the right hand These things are absolutely fixed in our military customs and have been so throughout history.

Again, in obedience to the universal need for barter—so Dr Gould points out—the primitive practice was counting with the low numbers, one to ten The fingers of the free dextral hand were first used, and all fingers are now called digits, as are the figures themselves, and the basis of our numbering is the decimal or ten fingered system

The second important fact in human anatomy is that all our voluntary movements are directed and controlled in the cerebral structure and organization The brain has two hemispheres, of which the right presides, by means of certain decussating nerve fibers, over the left side of the body, while the left brain presides over the right side And functional differences in the two sides are connected with and contingent upon differences in the two hemispheres The left brain, in all right handed people, is more highly developed than the right brain It is said that this greater development of the left brain in the right handed is so because the heart being on the left side of the body, sends its blood with greater force and directness to the left brain. It does send the blood more directly into the left side of the neck, but the flow of blood at the base of the brain is so equalized in the "circle of Willis," that the theory here stated can hardly be accepted as conclusive Besides, it is contradicted by the cases of left-handedness (which make up about four per cent of humanity) in which the heart is on the left side, precisely as with the right handed

An extremely important anatomical consideration is that in right-handed people the "speech center" is situated in Broca's convolution in the cortex of the left frontal lobe, while in left-handed people the speech center is in the same position, but in the right frontal lobe Now it has been found that damage to Broca's convolution in the left hemisphere deprived the right handed man of speech, which is unimpaired in the left handed man under the same circumstances, the left handed man would suffer in the same way, were

A NEW TELEPHOTO CAMERA

# THERMAL TREATMENT OF STEEL INGOTS

BY J. F. SPRINGER

There are two considerable imperfections which accompany the casting of steel ingots. The more conspicuous one is that of the pipe. This is a conical cavity which forms in the upper portion. In Fig. 1 we have in the center two longitudinal slabs taken from steel ingots which exhibit the pipe very clearly. The usual explanation of this curious formation regards it as a consequence of contraction. A mold full of molten metal cannot be full when the ingot has cooled off. There is in fact a volumetric loss of perhaps 5 per cent. But this does not account for the form of the pipe. Why should it be conical? It has been suggested that perhaps contraction at the moment of solidification controls this matter. To this, however, the answer is made that gray cast iron expands at this moment and yet it forms a pipe. Whether steel expands or contracts in the act of freezing no one seems to know with any certainty. But steel ingots form decided pipes as any steel makers will tell you. Prof. Howe has proposed an explanation which may help us somewhat. When the exceedingly hot steel is teemed into the mold it finds the walls and bottom of that mold at a very low temperature, comparatively. These molds involve quite a large mass of material as may be understood by noting the substantial character of those shown in Fig. 2. Their cooling effect is consequently a considerable factor. The first solid metal of this cooling ingot will constitute a shell conforming to the sides and bottom of the mold and containing a heavy mass of molten steel. Now, whether expansion or contraction takes place at the very moment of freezing, the steel of this shell will undoubtedly steadily contract. As this goes on, it meets resistance from the weight of the liquid within. Prof. Howe thinks that at times the elastic limit will be exceeded. There would thus arise a tendency to a "set," with the shell upon final cooling larger in cross section than would otherwise have been the case. Of course, the solidifying material contacting with the shell on the inside will cling to it. And further, one may conceive that, as the shell thickens, successive layers will come to normal temperature with expanded cross sections, for reasons similar to those controlling the outer shell. If so much is granted, it is easy to see that there is a tendency to leave the region of the axis empty. There is, however, another tendency at work seeking to nullify this. This is the gravitation of the fluid metal. This tends to fill up the pipe at the bottom. And so the lower portion of the ingot becomes solid throughout. But this transference of material from points above to points below impoverishes the upper portion, with the result that a pipe really forms, and that it is more extensive in cross section as one ascends.

To eliminate the pipe many procedures have been employed. These divide themselves into the mechanical methods and thermal ones. Perhaps the most successful process which has yet found its way into commercial practice is the Harmet procedure described in an article by the author in the SCIENTIFIC AMERICAN for May 29th, 1909. Methods, such as this, operate with a view of eliminating the pipe through the forcing in of its walls upon themselves while the interior of the ingot is in a liquid or plastic condition. The elaborateness of the apparatus necessary, and the length of time required, are serious considerations which operate against some, at least, of the mechanical processes. But efforts have been made to solve the problem by thermal means. If the steel at the top could be kept highly liquid until the lower part of the ingot becomes solid, then with such a reservoir perhaps the pipe could be progressively filled up as it formed. Upon some such fundamental idea the thermal processes depend. Krupp is said to have poured molten slag upon the tops of the ingots. Apparently but little is known of the measure of success. This might, perhaps, provide a good method. The slag would furnish considerable heat. Its lower specific gravity would prevent any mechanical penetration into the steel of the ingots. It has been found that, if ingots are cast, having a considerable taper with the large end up, the pipe will be reduced. In fact, a very considerable shortening has been accomplished in this way. Experiments have been tried where the metal was steel, zinc, and wax. All show improvement. No doubt this effect is due to the retardation of the cooling thus effected at the top by the provision there of a larger mass of metal. That is to say, the pipe is shortened if cooling is accomplished from below. There is, however, a strong objection to this method in that, although its length is reduced, the pipe is now located in the large end, and thus involves more metal in proportion to its length. Its corrective influence is thus discounted somewhat. There is another objection on the score that this method would involve complications in stripping the molds from the ingots. However, that a large source of heat at the top is of advantage is further testified to by certain experiences had with thermit. It has been found that by introducing this compound by means of a rod into the upper portion of an ingot, the pipe could be somewhat shortened. This result is, no doubt, due to the considerable heat set free upon the chemical reaction taking place between the thermit and the molten steel. The experiments with wax ingots carried out by Profs. Howe and Stoughton give evidence in the same direction. An account of these experiments may be found in an article by the present writer in the SCIENTIFIC AMERICAN for April 24th, 1909, where the marked difference in the length of pipe effected by casting with the big end up and the reverse is well shown by ingots Nos. 4 and 5. In the cases of ingots Nos. 6 and 7 we have the contrast realized by keeping the temperature hot at the top and cool at the bottom and *vice versa*. The difference measured in percentage of ingot preserved from piping amounted to 48 per cent. This advantage of nearly one-half the whole ingot was in favor of the hot top. Of course, these experiments were carried out in wax and not in steel. At the same time, they have their weight as corroborative evidence. Some years ago experiments were tried with steel by what may be called the overflow method. This is Prof. Sauveur's process. A number of molds were arranged in a way not unlike that disclosed in Fig. 3. By pouring continuously into the one on the left all may be filled. It was thus found upon one or more occasions that the first and second ingots whose heads were for the longest period kept hot and provided with liquid supplies of steel, disclosed no pipes. The next two had small pipes, involving about 4 or 5 per cent of the ingot length.

Now all these experiences prepare us to expect a decided success from the Riemer hot top process as used in Germany. This inventor applies a gas furnace to the ingot top. Apparently, however, others had had a similar idea. It would seem that their processes received but inconsiderable attention. Now Riemer not only applies his furnace but he applies it at once. Further, he provides an immense supply of heat. He thus prevents any tendency to the formation of a crust over the top. However whether we understand why it should seem necessary to furnish heat not only in great amount but with great promptness the fact

(*Concluded on page* [illegible].)

# EGGS OF CURIOUS FORMS

BY PERCY COLLINS

When we consider that with the exception of the class mammalia, practically every creature dwelling upon the earth at the present moment began life within the walls of an envelope popularly termed an egg, it becomes clear that the appellation must do duty for a very varied assemblage of objects. Not many people are aware that even the mammals (or animals that suckle their young) include several egg-layers, yet such is undoubtedly the case. These strange creatures are all native of that continent of animal curiosities, namely, Australia, although two of them—the echidnas—are also found in New Guinea. These echidnas are queer ant-eater-like animals, of whose habits comparatively little seems to be known, save that they subsist mainly on insects, and that they really do lay eggs.

Much more detailed accounts are extant respecting the habits of the duck bill *Ornithorhynchus paradoxus* (as science terms it) is not unlike a gigantic mole in shape, save that it possesses a remarkable tail and feet and bill of duck like design. Its habits closely resemble those of the common water rat. Frequenting the streams of southern and eastern Australia, it makes its nest in a burrow in the bank. Here Mother Duck-bill lays two white, flexible-shelled eggs, about three-quarters of an inch in length. When first hatched, the tiny duck-bills are both blind and naked, but in process of time they acquire the adult characteristic, and issue from the nest hole to feed and frolic in the river with their parents.

Leaving now the mammalia we find that all known birds lay eggs, the largest being that of the ostrich. Many of these eggs come from Africa, and after being scratched, painted, "poker worked" or otherwise adorned, are used for decorative purposes. Thus we are all familiar with them, and can realize that the contents of one would form a bountiful meal. But the ostrich's egg would have appeared quite small be-

# CURIOSITIES OF SCIENCE AND INVENTION

### MOTOR-CYCLE AUXILIARY FOR BICYCLES

A power attachment for bicycles has recently been invented which calls for no structural alterations to be made in the ordinary bicycle and which can be attached or detached in a few minutes. The device comprises a small auxiliary wheel 20 inches in diameter fitted with a light motor which is connected to the rear wheel of the bicycle. An ingenious pivoting

A POWER ATTACHMENT FOR BICYCLES.

arrangement allows the wheel a peculiar lateral and vertical movement, so that the steering of the machine is in no way affected and permits the wheel to glide over obstacles or rough ground without transmitting any shock or vibration to the rider.

The motor is a small air-cooled, horizontal, two-stroke engine with a specially designed hub to which the power is transmitted through a six to one reducing gear. The magneto ignition and vaporizer are mounted on the same plane, and in line with the engine, so that the whole is rendered very compact.

The engine is valveless, the inlet and exhaust being governed by ports, alternately covered and uncovered by the piston. It develops 1¼ horse-power.

To attach the motor wheel to the ordinary cycle, it is only necessary to remove the nut of the back wheel spindle on the chain side of the machine, and to attach the frame of the auxiliary wheel to the spindle and bolt it up—an operation occupying a few moments. A single-lever regulator controlling the motor is clipped to the handle bar, the connection with the motor mechanism being a flexible wire. This single lever controls the action of the engine to a nicety.

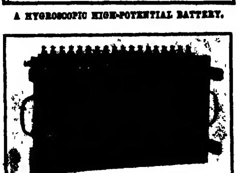
The wheel complete weighs only 25 pounds, and the motor is capable of driving the bicycle at an average speed of 16 miles per hour on an ordinary road, with a maximum speed of about 18 miles on the level. The fuel tank in the mud guard is of sufficient capacity to carry the motor 100 miles.

### A NOVEL HIGH-POTENTIAL PRIMARY BATTERY.

A new and ingenious high potential primary battery, the purpose of which is to supply electric charges at known potentials, was recently exhibited before the English Physical Society. The positive element of each cell consists of a small carbon rod, while a strip of pure zinc comprises the negative element, the electrolyte being a solution of calcium chloride.

The connected ends of the elements, which are mounted in parallel rows of 25, are buried in paraffin.

A HYGROSCOPIC HIGH-POTENTIAL BATTERY.



THE BATTERY INVERTED TO SHOW THE ZINC AND CARBON ELEMENTS.

Contact between the free carbon and the zinc elements is just broken by a small pellet of paraffin, and the liquid is retained between them by capillarity.

The electrolyte comprises a saturated solution of calcium chloride which has been exposed to the air. Being hygroscopic it will absorb water until a certain equilibrium strength is obtained, this factor depending on the humidity of the air and the temperature. The electromotive force of each cell differs from one volt by only two or three per cent if exposed to very different conditions of temperature and humidity, but it has been kept steady to within 0.1 per cent for two or three consecutive days.

In conjunction with an electrostatic voltmeter, the battery is very convenient for the following purposes: In all experiments involving the use of a quadrant voltmeter, as the needle can be charged to any desired voltage up to 1,000 volts, since the battery is so designed that one or any number of elements can be taken, for the comparison and calibration of electrostatic voltmeters, for the comparison of capacities, and for the measurement of high resistances by the method of discharging a condenser through them and noting the time taken.

### DETECTOR FOR FIRE-ALARM BOXES.

The problem of so designing a fire alarm box that it can be opened and operated by any one in an emergency and yet will tend to prevent the sounding of false alarms, is one that has engaged the attention of inventors for many years. A very ingenious solution of the problem is presented in the accompanying illustrations. The alarm box is closed by a cover which has to be raised as shown in one of the illustrations to permit the operator to insert his hand through an opening and release the alarm mechanism. At the moment of the release a handcuff closes over the wrist of the operator, as illustrated in another photograph. The handcuff is not chained to the alarm box; for this would make a prisoner of the operator of the alarm, whose services might be badly needed at the fire. Instead, however, the handcuff

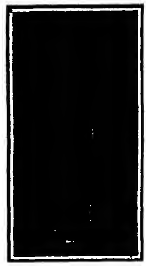
The alarm box closed. Operating the alarm. The operator handcuffed.

DETECTOR FOR FIRE-ALARM BOXES.

serves merely for identification. It is made of such form that it cannot be concealed under the coat sleeve and it betrays the sounder of the alarm to the general public, and is an honor to a man unless the alarm is a false one. Not until the fire chief has arrived with a special key to fit the handcuff may the device be removed. This system is also applicable to boxes which are locked. It frequently happens in such cases that the keys are loaned out and it is impossible to determine who sounded the alarm even when it is known whose key is missing.

### CAPPING MILK BOTTLES BY MACHINE.

Greater precautions must be taken in handling milk than any other form of food, because it is such an excellent medium for breeding germs. Hand work is always objectionable because of possible contamination from unclean fingers. Heretofore milk bottles have commonly been capped by hand. Now a simple machine has been invented for doing this work which should be of value to small as well as large dealers. The machine consists of a magazine and a means of taking one cap at a time from the magazine and pressing it firmly into place on the top of the milk bottle. It not only adds to cleanliness in dairies, but saves time, inasmuch as it is many times more rapid in the operation of capping bottles than the human



PORTABLE BOTTLE-CAPPING MACHINE.

hands. One type is portable and is operated by a quick squeeze of the handle. The other type consists of a battery of cappers which will operate to cap a number of bottles at once. The magazine takes the caps in packages from the machine which made them and obviates the necessity of handling the cap itself.

A MACHINE FOR CAPPING FOUR MILK BOTTLES AT A TIME.

### UMBRELLA SHELTER FOR AUTOMOBILES

It is impossible to enter a vehicle on a very rainy day without getting wet, because the umbrella must be lowered before one can step inside. Surely it is just as necessary to provide vehicles with some sort of a shelter, such as the awning of a store or the marquee of a public building. However, anything projecting from the side of a vehicle would be objectionable. The difficulty is surmounted quite cleverly in the automobile, which is illustrated in the accompanying engraving. A collapsible awning is attached to the top of the automobile, and also to the top of the door, so that when the door is opened to admit the passenger or to allow a passenger to alight, the awning will open and protect him from the rain while he is raising or lowering his umbrella. When the door is closed, the awning shuts up like a fan.

UMBRELLA SHELTER FOR AUTOMOBILES.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

ARCH SUPPORT.—P Hammer, Marlboro, N. Y An object of this invention is to provide an attachment for the shoe which will comfortably support the arch or instep at all points, and will at the same time provide adequate ventilation for the interior of the shoe without admitting water from the streets in which the shoe might happen to be placed.

### Of General Interest.

FOUNTAIN-PEN —C H. Mantlinu, and C. Dunn, New York, N Y In this instance the aim is to provide a fountain pen having a screw cap which forms an ink tight joint when in position to cover the pen point, so that the ink cannot escape to any part of the holder or pen section, and in which evaporation of the ink in the barrel is prevented.

HELIOGRAPH —T J Maiers, New York, N Y An object of the invention is to provide novel details of construction for an instrument which will reflect light rays from the sun or an artificial source, in radial lines, towards all points of the compass, and more particularly in a horizontal plane

TREE-SPRAYER —F G Hayes, Sharon, Pa Mr Hayes provides a light apparatus adapted to be operated from a position much lower than the usual spraying towers, provides an apparatus for directing the fluid being sprayed, which may be extended or retracted from the operating station, provides for extending and retracting the operating position of the spraying device and provides a sprayer operable by one person.

SUPPORT FOR DISPLAY MATTER —T Hasselhoffer, New York, N Y This invention is especially applicable to theatrical advertising for use in hotels, railroad stations, and other public or semi public places in large cities, although it is evident that the invention may be employed in connection with advertisements, signs, or displays of other character or matter

RECEPTACLE-CLOSURE —R G Adams, Hayward, Cal The object here is to construct the closure so that the bail and the cam member may be turned relatively to each other and to the cover and receptacle, whereby the parts may be easily and expeditiously assembled, and, further, to so construct the bail and cam member that they may be stamped from sheet metal and the cost of manufacture thus brought within the limits of practice

MANUFACTURE OF BREAD —C A Heudebert, 8 Rue du Chemin de Fer, Nanterre, Seine France This invention relates to a novel gluten bread, very rich in nitrogenized substances produced by the incorporation of a soluble casein obtained from milk It is of agreeable taste such as is unattainable in the ordinary process Mr Heudebert has also invented a process which permits of adding the casein in large proportions to flour rich in gluten and permits the complete incorporation of the casein, thus avoiding the formation of lumps.

### Hardware and Tools.

WIRE ROPE CLAMP —C A McCarthy, Hattiesburg, Miss. One of the important features of this invention is the means whereby the inventor provides a practical one bolt clamp, and in doing this he arranges grooves in close proximity to the bolt holes so that the strain of the bolt is exerted almost directly upon the cables when the latter are in the grooves and upon the outer side of the socket receiving the bolt head he provides a square portion which forms a wrench head, so that the wrench can be put on the head and coöperate with the wrench on the nut so as to tighten the clamp upon the cables.

ATTACHMENT FOR ANVILS.—A R. Everett Brookfield Township, Ohio. The object of the invention is to provide a device which can be operatively positioned on an anvil by means of a treadle, thus obviating the necessity of the operator using his hands for this purpose, and which can be inoperatively disposed when not in use

BUCKLE.—J F Dunn, New York N Y In its use as a belt buckle there is a possibility of ornamentation of the exposed portion. In the present instance the body portion of the buckle is formed from a solid plate, the outer surface of which is continuous and adapted to form a surface for ornamentation, such as engravings of initials, embossing, or producing repoussé effects.

### Household Utilities.

MOP AND BRUSH HOLDER.—F. Dueling, Portland, Ore This holder is adapted to receive and hold mops, rags, or scrubbing brushes, the holder is readily and quickly adjustable for holding articles of various sizes and characters, and is also adapted to maintain an adjustable and resilient grasp upon the article used in connection therewith.

### Machines and Mechanical Devices.

METHOD FOR CASTING METAL BARS, WIRES, AND PIPES —F W. Winner, Han-Yang, China. This is an improved method of casting metal bars, wires, and pipes of any length and diameter and of any cross-sectional shape, which is done by passing the metal in a molten state into a chilling mold and revolves the mold about a point, whereby the metal, after being chilled, will be assisted in its discharge from the mold by the centrifugal force developed by the revolution.

GLASS-MOLDING MACHINE.—W J Miller, Coffeyville, Kan. The object here is to convert semi-automatic machines of a certain type into practically automatic machines. The invention consists in part of a pair of shears arranged at the charging position and adapted to cut off the glass as it is inserted into molds by the gatherer the shears being actuated by the punty or pontel as the glass is placed in the mold

Note.—Copies of any of these patents will be furnished by Munn & Co for ten cents each. Please state the name of the patentee title of the invention, and date of this paper

[See note at end of list about copies of these patents.]

Acetylene generator, C O Wakefield ..... 952 286
Acid obtaining acidylic derivatives of esters of dimethylamino-dimethyloxyaceti. E. Fourneau ..... 952,828
Acids preparation of esters of oxyamino E. Fourneau ..... 952,006
Adding machine, E. M Plummer ..... 952,137
Advertising closet seal cover L. D Castle ..... 952,231
Air brake W S. Hilbray ..... 952,298
Air brake system, direct, A Dean ..... 951 987
Air brake systems, cock controlling device for V J Koehler ..... 952 131
Alloy, high resistance iron, W B Whitney ..... 952,299
Alloy, steel, S. S. Wales ..... 952 591, 952,893
Anchor for airships and the like, safety F von Ehrenberg ..... 951,942
Angle pieces for use in structural frames metallic standards, etc , rigid metal, P Phipps ..... 952,016
Apron blacksmith's, E. P Bockmann ..... 952,179
Automobile controlling means, H E. Coffin ..... 951 984
Axles, driving mechanism divided, O H. Johnson ..... 951 914, 951 913
Bag See Clothing bag
Bag fastener J B Isidor ..... 952 199
Baling press, cotton, M. A. Withers ..... 952 291
Barge coal loading W Yoha ..... 952 291
Barrel bung C Hoff ..... 951,912
Basket making machine W F Barnes ..... 952 406
Bath tub trap waste and overflow pipe attachment, D. J McIntyre ..... 952 091
Battery holder electric, C T Mason ..... 952,208
Bearing antifriction, L. H Seubert ..... 951 547
Bearing roller, J Ramalie ..... 952 198
Bell door, W H Moore ..... 952,120
Bicycle brake controlling device, R. Peda cane ..... 952 349
Billiard cue J Baumle ..... 951,790
Blind operating device J Bolewics ..... 952 004
Blind slat operating device, J Bolewics ..... 951 085
Board, J T Ferres ..... 952,074
Boats safety device for submarine, W A Stevenson ..... 952,370
Boiler, J G Hayden ..... 952,429
Boiler setting M. H. Cheney ..... 952,282
Book holder, R. G Eghian ..... 952,105
Book marker, Chelsea & Benedict ..... 952 185
Bookbinding M C Namer ..... 951 865
Bott, R. Daniel ..... 951,986
Bottle and stopper A. T Wasserwetsch ..... 952,247
Bottle holder milk, F M Farber ..... 952 107
Bottle, non-refillable, H E. Cronk ..... 951 959
Bottle, non refillable, E. O Martin ..... 951,967
Bottle, non-refillable, F Adams ..... 952 400
Box See Fruit box.
Box opener J Trembley ..... 951 800
Box or receptacle Kreuzkamp & Bowman ..... 952 383
Brake beam C H Williams, Jr ..... 951 891
Brake head for solid beams, reinforced, C H Williams, Jr ..... 951 880
Bread, peppermint, M A Heinser ..... 952,114
Brick drying shed, E H Callaway ..... 952,230
Brick, tile, or other articles, apparatus for baking, glazing or enameling L. House ..... 952 180
Bridge, suspension W A Wood ..... 951,871
Brush cutter, W Gilbert ..... 951,812
Building block, D. McIntyre ..... 952 080
Buoy, reel life, A. Rust ..... 951,846
Cabinet, W M Shields ..... 952 146
Cable reel, G E. Lynch ..... 951,856
Calculating machine A Burkhardt ..... 951 962
Calculating machine R. Jahns ..... 952 257
Can cover holder, H M F Leighty ..... 951 816
Can filling mechanism, E. Schilling ..... 952 145
Can opening and closing implement A R. Rowe ..... 952,170
Cane and camp stool combined M. Killian. ..... 952 235
Car brake, J W Lamoreaux ..... 951 820
Car coupling, S. Winter ..... 951,896
Car door, grain, J E. Fawcett ..... 952 319
Car door hanger, W E. Kilmer ..... 952,120
Car door lock, J F Billy ..... 952 411
Car, dumping, A Becker ..... 951 983
Car fender, motor, E. Forward ..... 952,243
Car, gondola, A. Becker ..... 952,026
Car grain door, C. C French ..... 951 800
Car stake socket, Bald & Crotty ..... 952,008
Car underframe, A. Becker, 952,027, 952,028 ..... 952,089
Car underframe, railway, J G. Bower ..... 951,984
Carbureter, H M Van Buren ..... 951 823
Carbureter, F. W. Hagar ..... 952,338
Carpet fastener, stair, H. G. Adams ..... 952,401
Carrier See Molder's flask carrier
Case filler S. M Hastings ..... 952,346
Casing, puncture proof, English & Lichtenstein ..... 952 072
Cereal steeping apparatus, A Peltzer ..... 952,186
Chair cane R. Tam ..... 951,857
Chair fan attachment, rocking A. A Brodeur ..... 952,008
Chair head rest, barber, A. L. Undeland, reissue ..... 13,094
Check book M Shoemaker ..... 952,147
Chocolate and cocoa, dietetic Tallott & Eckardt ..... 952,418
Chuck, T J Fegley ..... 952 320
Churn, C Austin ..... 952 286
Circuit breaker P G Tomas ..... 952 153
Clamp, N Bouma ..... 952 182
Clock, intermittent alarm, W E Porter ..... 952 113
Clock movements and the like, motor for S. W Bramley ..... 951 903
Clothes moistening device T Hase ..... 951 901
Clothing bag A F Bornol ..... 952 181
Clutch, T O Johnson ..... 951 902
Clutch device W Holdberg ..... 951,889
Clutch, hydraulic C A Schlachter ..... 952 217
Clutch operating mechanism for cranes, Rundle & McDougall ..... 951 843
Coal distributing apparatus, A Sommer ..... 952 020
Coal tar means for removing free carbon from Lowry & Bernhard ..... 951 891
Coaster brake, F W Fox ..... 951 880
Coating machine liquid G H Benedict ..... 952 083
Cock for steam boilers try Kelly & Gerds ..... 952 156
Cock, water S Reeck ..... 952 048
Collars, machine for folding and ironing the edges of C Rissenweber ..... 951 917
Comb cleaning holder automatic C N Harrington ..... 952 328
Composing and distributing machine typographical Holbourne & Longhurst ..... 951 948
Composing machines, means for leveling matrices in typographical C Muehleisen ..... 952 271
Composition of matter, Vastag & Horvath ..... 952 289
Concentrating apparatus, H S. McKinley ..... 951 964
Concrete block C A. Buskirk ..... 952,305
Concrete cisterns, sewers and the like form for G F Boswell ..... 952 068
Concrete construction tension member for T W Jenks ..... 952 281
Concrete fence post A O Cunningham ..... 952 071
Concrete walls, apparatus for molding H F Crowe ..... 952 238
Condenser, surface C G Curtis ..... 952 102
Container T L. Smith ..... 951 853
Conveyer D W Sullivan ..... 952 381
Cooker, compressed steam N T Hanson ..... 952 113
Coop brooding and nesting Prescott & Whittier ..... 952 155
Corset stay J H Wilson ..... 952 068
Cot collapsible R H Rasmussen ..... 952 211
Cotton chopper, G P Arthur ..... 951 978
Cotton chopper, R R Gibson ..... 951,107
Cotton chopper W Dittrich ..... 952 310
Cotton topper Bickers & Lee ..... 951 796
Coupling See Car coupling
Crate, folding B. K Boyd ..... 951 903
Cream separator, N S Sprague ..... 952,220
Cultivator, R L. Kilpatrick ..... 951 950
Cultivator R E. Held ..... 952 115
Curler hair, W M Williams ..... 952,808
Curling device hair H W Reynolds ..... 952 138
Curtain pole fare W T Thurber ..... 952 174
Curtain rod J W McMahon ..... 951 853
Cuspidor V H Gleason ..... 952,247
Cutter bar A Dahms ..... 951 865
Cutters, root gage for Smith & Braun ..... 951 072
Cycles combined free wheel clutch and back pedaling hand brake for T C Hancock ..... 952 041
Dental instrument B. W Wallace ..... 951 880
Dental instrument, B. W Wallace 951 880 ..... 951 881
Dentist's bridgework W A Barns ..... 952 220
Dentist's mandrel W B Miller ..... 952 437
Derrick dumping device P H Peters et al ..... 952 330
Developing apparatus, A P Cutler ..... 951 983
Digester and extractor inclined rotary H R. Yarnall ..... 952 221
Digging apparatus S. B Fleming ..... 951 907
Display rack for burial caskets foldable C O Whitcomb ..... 952 058
Display stand jewel G C Heuckert ..... 952 141
Distilling device D A Neuninger ..... 952 348
Distributor J G Hilms Jr ..... 951 815
Door check and holder O B Hendricks ..... 951 817
Door operating mechanism dump O W Meissner ..... 951 884
Door supporting means W B Shaw ..... 951 971
Doubling mechanism I C Steele ..... 952 002
Drinking cup A R Husel ..... 952 107
Drinking cup, sample J G Sharon ..... 952 168
Driving gear, J M Smith ..... 952 141
Drying and charring materials, apparatus for, N K H Ekelund ..... 951 804
Drying textile yarns, fabrics, and other materials, apparatus for I Turtur ..... 951 840
Dumping mechanism M A Young ..... 952 169
Dust remover, suction, F X Frank ..... 951 800
Eaves trough guard F M Dellsch ..... 951 803
Egg beater, H F Neber ..... 951 831
Egg candling and packing machine H Pieper ..... 952 862
Egg tester A L. Anderson ..... 952,174
Electric apparatus, magnetic core for W C Fish ..... 952,105
Electric controller, Smith & Larsen ..... 951 853
Electric iron, F Trott ..... 952 990
Electric switch F W Smith ..... 951 851
Electric time switch G Lucht ..... 952,123
Electrical distribution system A S. Hubbard ..... 952 332
Electrical indicator C Wirt ..... 952 163
Electrode protector H C Harrison ..... 951 880
Electromagnet S. P Thrasher ..... 952,168
Elevator shaft construction E Cahill ..... 952 415
Elevators, limit stop for hydraulic T B Brown ..... 952 107
Elevators plunger guide for direct plunger Lahman & Smith ..... 952,044
Embroidery machine spool holder J Frey ..... 951 810
Engine See Internal combustion engine
Engine J A Dowling ..... 952,811
Engine controlling mechanism explosive W J McVicker ..... 951 831
Engine cylinders cooling device for explosive F M Sizemore ..... 952 148
Engine driving mechanism, paper refining F B. Reecher ..... 951 910
Engine starting device J T Barber ..... 952 405
Engines, automatic steering means for plow C A Frisz ..... 952 017
Engines, operating oil E Higgins ..... 952,410
Engines, throttle operating mechanism for explosive, Winton & Anderson ..... 952,398
Faucet W J Sullivan ..... 951,855
Feather holder and support N Force ..... 951,046
Feeding device automatic proportional E. I Noxon ..... 952 134
Felly finishing machine C W Borg ..... 951 981
Fence post D H Miller ..... 951 958
Fence stretcher M Wilson ..... 951 970
Fence waterway stock, E E Tyler ..... 952 123
Fertilizer distributer T S Ingram ..... 952 252
Fertilizers preparing mineral E. Pohl ..... 952 378
Field or hunting flask Rorger & Ambon burner reissue ..... 13 093
Filling device for scraper blades, J White ..... 951 901
Fire alarm intercommunication system A D Wheeler ..... 952 024
Fire escape J Lachett ..... 951 821
Fire escape S. Davidson ..... 952 230
Fire escape Erwin & Meyer ..... 952 115
Fire resistant shutter J G Wilson ..... 951 867
Firearm H S. Lewis ..... 952 388
Fishing apparatus, container for J M Fitzworth ..... 952 314
Flagstaff J K Moore ..... 952 045
Flashlight H A. Whitfield ..... 952 304
Flushing apparatus W L. Deming ..... 952 240
Flying machine, Strich & Weis ..... 952 316
Flying machine motor, A. Wunderlich ..... 952 107
Forge T J Ward ..... 951 802
Fork and scraper, J Nichol ..... 952 345
Form shoulder presser J M Mela ..... 952,377
Fresser G F Dickson ..... 952 050
Fruit box, collapsible W, H Bronner ..... 952 302
Fruit syrups, or the like, receptacle for dispensing crushed L. A Becker ..... 952 409
Funnel J E W & C E. Richards ..... 951 848
Furnace. See Smelting furnace
Furnace, W A Norton ..... 952 047
Furnace, V H. Hobson ..... 952,431
Furnaces, feeding mixed fuels to A S. Mann ..... 952,288
Game apparatus, E. K Eldridge ..... 951 805
Garbage press P H Taylor ..... 952 231
Garment hanger H S. Rathbun ..... 952 250
Garment support and form combined H Klingenfeld ..... 952 203
Gas apparatus, vertical retort J H Taussig ..... 951 836
Gas burner Mintier & Jennings ..... 951 828
Gas from oil apparatus for generating P Meyer ..... 952 127
Gas from peat making I J Buckley ..... 951 799
Gas igniter and extinguisher J I Landes ..... 952 200
Gas meter, E H. Halsey ..... 952 110
Gas producer M E Crowell ..... 952 237
Gasket packing J W Miller ..... 952 128
Gasolene burner A J Blackford ..... 952 412
Gasolene indicator M H Creslon ..... 952 458
Gearing E Felx ..... 951 815
Gearing, Rodgers & White ..... 951 905
Gearing roller grip for band W Trowbridge ..... 952 130
Glass, apparatus for rolling wire, A Meyer ..... 952 120
Glass making imitation art A Fassley ..... 951 879
Glass manufacture of plate F L. D Wadsworth ..... 952 300
Glass method of and apparatus for production of sheet J Player ..... 952 454
Glass plates, apparatus for silvering Glaser & Wuhlblatt ..... 952,191
Glass tiles apparatus for forming W T Nicholls ..... 952 272
Globe collapsible geographical H H Van Keuren ..... 952 110
Gold and silver from ore slimes extracting A P Crowe ..... 951 040
Grading machine road B. Whittemore ..... 951 805
Grain bin portable E E Nonquist ..... 952 651
Grain divider Saudel & McLaun ..... 952 102
Grass crimping machine E Wessel ..... 951,803
Grate bar H W Blanchard ..... 951,797
Grate bar J & W Reagan ..... 952 215
Grinder and polisher, H Adam ..... 952,809
Grinding mill, roller F I Matthews ..... 952 289
Gripping mechanism C Van Middlesworth ..... 952 285
Gummed strip serving apparatus, F E. Francis ..... 952,186
Gun for scaring birds or like purposes automatically operated W Roeder ..... 952 018
Gun sighting apparatus, H Schneider ..... 952 368
Guns cartridge feed mechanism of Maxim G T Buckham ..... 951 989
Hair waver A. H Bowers ..... 951 798
Hammer power G Jackson ..... 952,205
Hammock device E A Wilkes ..... 951 894
Hammock support H W Beal ..... 952 228
Handle See Pump handle
Harrow C H White ..... 951,934
Harrow adjustment, disk, R H McCaughey ..... 952,341
Harrow draft bar S. A D McGovern ..... 952 210
Harrow drag A H Imrk ..... 952 281
Harrow scratch E Mahone ..... 952,134
Harvester F J & W N Triplett ..... 952,384
Harvester combined B Holl ..... 952 830
Harvester reel J H & C D Hinkle ..... 952,249
Harvesters stalk packer for corn W H Tilson ..... 951 922
Hay press, J W Guynes ..... 951 088
Hay press, A H & L P O Quinn ..... 952,847
Hay tedder E P Curtis ..... 952 228
Hay tedder H M Hughes ..... 952 250
Headlight automobile W H Tunne ..... 952 055
Heating furnace W Fisher ..... 952 426
Hinge I Barlow ..... 951 900
Hinge F W Farnam ..... 951 944
Hinge E L. William ..... 952 060
Holdback W J Parvin ..... 951 850
Horn support F L. Aiken ..... 952,256
Horseshoe A Myer ..... 952 206
Humidifier F B Comins ..... 952 234
Hydrocarbon burner J L. Henry ..... 952 194
Ice cream freezer G F Dickson ..... 952,031
Ice cream freezer A H Max ..... 952,239
Illuminating and projecting apparatus solar W T Skilling ..... 951 850
Incinerator, F I Decaire et al ..... 951 905
Inkstand J J Hoey ..... 952,116, 952 720
Internal combustion engine L. F Meade ..... 952 438
Iron melting and refining H Johnson ..... 952 390
Ironing board A M Harman ..... 952,427
Ironing stand W Bennett ..... 952 207
Jack, H B Mueller ..... 952 130
Jack block J A Gray ..... 952,825
Jack box cordless H H Rugh ..... 951 918
Jewel mounting F White ..... 951 896
Jug and other hinged lid receptacles molasses, J F Haffey ..... 952 426
Kiln feeding apparatus, H Hoehne ..... 951 911
Knobs on spindles means for adjusting and locking door C D Noack ..... 951 830
Labeling machine bottle M E Noyes ..... 951 837
Ladder extension J A Johnson ..... 952 432
Ladles, trunnion support for dumping F C Sherman ..... 952,368
Lamp, burner H J Ballentine ..... 951 791
Lamp receptacle for electric signs, electric, F W Ruby reissue ..... 13 095
Lamp socket electric J G Peterson ..... 952 270
Lanterns, slide and shutter operating device for magic Oldfield & Nims ..... 952 346
Latch door T M Harski ..... 952 277
Latch door H W Struge ..... 952 378
Latch gate D B Chambers ..... 952 020
Lathe Smith & Rigby ..... 952 149
Lathe car wheel Stebbins & Bears ..... 952,048
Lathes and like machines adjustable collet for P F Schultis ..... 952 364
Laundry iron, J H Adams ..... 952,285
Leveling rod G de la Pena ..... 952 275
Light See Flash light
Limb artificial J E Hanger ..... 951,969
Line casting machines matrix for J R Rogers ..... 951 906
Line chalking device F W Hrda ..... 952 913
Linotype machine R F Wilson ..... 952 107
Linotype machines line controlled heating system for A. A Hill ..... 952 185
Liquid dispensing device H I Moore ..... 951 820
Liquid fuel burner I H Rycer ..... 952 772
Liquid material apparatus for agitating R N Towne ..... 952 222
Liquid separator F G Eppley ..... 951 806
Lock H F Kell ..... 952 118
Lock A C Jackson ..... 952 241
Locomotive system rack rail I A Trail ..... 951 942
Longitudinally movable element mechanism for controlling a J H Bellinger ..... 951 901
Loom Reulston & Fowler ..... 951 835
Loom automatic filling replenishing H Jamie ..... 951 010
Loom rack narrow ware W Watt ..... 952 150
Loom warp beam Gough & Hauder 952 226 ..... 952 227
Looms apparatus for operating picker motion for C Brakle ..... 952 096
Mail and the like, overhead carrier for F W Miller ..... 951 980
Malting or drying grain or the like drum for B Kissen ..... 951 835
Mash tubs drain attachment for J N Burner ..... 952 190
Massaging and the apparatus portable electric N H Le Fevre ..... 951 821
Match boxes means and the like receptacle for I F Whipple ..... 952 106
Measuring apparatus liquid F S Dennis Thorpe ..... 951 911
Mechanical movement J I Tauer ..... 952 183
Merry go round A H Towne ..... 952 242
Metal and glass cleaning articles of H I Mauby ..... 951 921
Metal composition of elements to be used for the manufacture of an improved quality of I R Bryson ..... 952 080
Metal mold I Mueller ..... 951 991
Metal pipe G A Lata ..... 952 077
Milk protector A & A Iske ..... 952 256
Milking machine teat cup F A Lane ..... 952 122
Miter box H S. Milks ..... 952 770
Mold J W Urie ..... 952 187
Molder's flask carrier J G Morrison ..... 951 831
Molding apparatus A H Ward ..... 951 801
Molding device J E. Le Sueur ..... 952 264
Molding machine J G Morrison ..... 951 830
Molding machine L. Parotti ..... 951 838
Molding machine W Lewis ..... 951 971
Mop head R R Brukeman ..... 951 821
Mower vertical lift C Maul ..... 952 125
Mower vine W I Hall ..... 952 080
Mowers, grass catcher for lawn C Clemens ..... 952 308
Mud guard attachment J A Stone ..... 952 144
Musical instrument pneumatic I d Kelly ..... 952 265
Musical pipe, A. V Chavers ..... 951,801

Musical time indicator, P Simpson 952,870
Nail extractor M Wenger 952,249
Napkin holder, F Dahlund 952,419
Nitrogen oxidizing atmospheric H Howard 952,248
Nut lock R Center 951,800
Nut lock, Steckman & Troutman 952,288
Nut lock, H B & J C Webiger Jr 952,425
Oil burner J D Pace 952,349
Ore crusher McKenzie & Laherty 952,046
Ore screen R I Akins 952,001
Ozone generator F M Ashley 951,789
Packaging machine B Hoyt 952,331
Packing G F Miller 951,827
Packing pad forming machine A C Peterson 951,841
Packing pad machine A C Peterson 951,840
Paper bags machine for making block A Henderson 952,175
Paper coating machine C F Pease et al 952,135
Paper fastener I G Fisher 952,323
Paper holder attachment S P Fitz 951,948
Paper manufacture of craped or goffered G Loebbecke 951,904
Pasteurizing apparatus, H E Weber 951,803
Pattern grading and cutting machine A F Prevlon 951,898
Pawl and ratchet mechanism W H Fishburn 952,052
Pen and pencil holder M A Dwinell 952,102
Penholder M E Farris 952,424
Photographic printing machines, exposure attachment for R N Kerr 952,334
Piano action H O Clark 952,417
Picture and like mount E and J Wright 952,202
Pipe cleaning machine D L Jobb 952,201
Pipe coupling W H Toner 951,899
Pipe covering J B d'Homergue 952,117
Pipe hanger G H Carleton 952,053
Pipe stem M Kolf 952,337
Plant protector I B Frily 951,807
Planter W G Johnson 951,818
Plastic articles mold in which to form L E Roberts 952,270
Plow J F Becker 951,792
Plow line holder T I Sjillers 951,854
Plug clean out I F Mahlin 952,078
Polishing means G P Courtois 952,180
Pool register K H Hess 951,887
Post See Concrete fence post
Posts anchoring base for P T Bailey 952,404
Potato digger W C Howe 952,082
Potato digger O W Jessup 952,200
Potato sorting machine Purdy & Spalcher 952,215
Pressing machine clothes J Gross 951,909
Printing machine W Scott 952,418
Printing plates making M A Droitcour 952,312
Printing press delivery board M A Droitcour 952,425
Printing press for printing from intaglio halftone printing plates H A W Wood 952,060
Protector A C Alexander 951,820
Pump J E & W E Hillmore 951,908
Pump H N Murchie 952,340
Pump ale C H Dalzell 952,440
Pump handle Sownak & Stetler 952,051
Pump jack J L Hendershot 951,816
Pump piston W C Buck 952,103
Pumping aquarium E E Aaron 952,204
Punch stitch removing H Johnson 952,341
Purse F M Stanley 952,370
Push button valve mechanical J G Waterman 951,803
Rail joint I L & F M Leasure 952,204
Rail joint W H French 952,724
Rail support, W Wilkens 951,928
Railway switches lever for J Leith 952,076
Railway third rail electric I L Edwards 952,104
Railway tie J F Weems 952,007
Railway tie J R McGuire 952,143
Railway tie H S Rogers 952,361
Railway trains system of electric signals or control for J T Thompson 952,064
Railway weed cutter Laas & Whitty 952,204
Raisin seeder W I Anderson 951,807
Ratchet wrench I Miller 952,140
Razor G & A H Frank 952,034
Razor safety I D Maxim 952,316
Razor stropping device F I Young 952,168
Reamer W Walth 952,138

(Concluded on page 267.)

A TRIP IN THE LARGEST BALLOON.

(Continued from page 256.)

thing else was a midsummer night's dream. It was only by an effort of reason, or when, through a powerful glass, we distinguished animals in motion, that we realized the home of seven hundred thousand souls to be other than a microscopically beautiful toy

"When nearly above the office of the Inquirer, we celebrated this occasion by flying our ballast and shooting upward, which turned us more to the east, and we were above the Delaware, at an altitude of about a mile Here we verified the fact that we could see with the naked eye the bottom of the river, and with a large spyglass clearly distinguished the great stones in its bed

"Indeed, one of our fellow voyagers insisted upon it that he observed the motions of the fish. Certain it was that the ripple of the plying steamers was most marked, and then we turned to the shipping Having taken a patriotic squint at the Island of Smith, and the still more celebrated Tinicum, we reached the Jersey side at five minutes past six, observing Camden in all its glory The current took us more directly toward the east, and we for half an hour or more followed closely the Camden and Atlantic Railroad, which could only be distinguished from the turnpikes by the aid of a glass. In the moving panorama, the fertile fields of East Jersey formed a most beautiful portion with the Rancocas and Cooper's Creek winding snakelike through wee oblong inmiosures, distinguished only by the different colors of ripe wheat, growing corn, and other tokens of peace and plenty Toward the ocean, a bank of cumulus clouds rose up, and in the west the city was growing dim. We passed over Haddonfield and near Long-a-coming and Waterford, then began to go much higher and faster, having passed right through a fleecy cloud Beneath us stretched almost interminable pine forests, with the white sand sparkling here and there in tiny patches We were at this time at the highest altitude attained during the trip, about three miles, and moving to the east at the rate of at least sixty miles an hour Here the earth appeared convex instead of concave, a phenomenon often observed and accounted for, but none the less curious, and the spirits of the party became almost as high as the barometric location of their bodies We individually got up the ladder into the hoop and insisted on singing songs, which, owing to the rarefaction of the air and the echo from the balloon, had quite a stentorian effect At this point, as we were far above the smoky haze surrounding the earth, and also the region of clouds, the sky looked more beautifully blue and vivid than can be conceived. The moon was almost as bright as it is usually at night, and the sun, which was nearly set to the poor people below, gave to the few clouds tints to us hitherto unknown

"We may here mention that during the voyage we brought 'Sol' up and down several times, thus having a variety of sunrises and sunsets within the space of minutes The atmosphere, even at our greatest elevation, was not so cold as was expected, owing to the rays of the sun being generally refracted from the hazy clouds below The chief physical manifestation of our situation was in the ears, for when descending from a more rarefied to a denser atmosphere there was a whizzing, much like that in the diving, and from the same cause.

"Although it had been the aeronauts' intention to reach the ocean, which now was visible, the sails on it being seen by the telescope, yet a delay of two hours, occasioned by the vastness of the preparations before starting, limited the time so that it was an alternative to land on a somewhat uninhabited coast without daylight to direct us to a proper spot, or take the back track. The latter course was most prudent in reference to the securing of the balloon, and as affording

(Concluded on page 267.)

A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

(Concluded from page 268)

better opportunities for its conveyance to Philadelphia So we came down very fast, aided more than was entirely desired by the falling dews, and the contraction of the gas after the sun's rays had so much diminished However by a wholesale throwing off of ballast, we kept up at a safe distance proceeding in a curve to the northwest, until observing that a crowd was gathering from all points of the compass in the neighborhood of Medford evidently calculating on our descent and shouting loud invitations, we gratified them and promised their assistance. A large number of willing men caught hold of our long trailing rope by Mr Lowe's direction Our gas was allowed to escape freely, and we landed on a large sand bar one of the best places that could have been selected, at a quarter past eight after about sixty miles of the pleasantest voyage it is possible for man, the unwinged bird, to take"

### VERTICAL PHOTOGRAPHY.

(Concluded from page 256)

ground is placed under the glass supporting the article to be photographed. The distance between the support and the background varies from three inches to eighteen inches The greater the distance the less reflection The color of the background is generally determined by the color of the object to be photographed When working under the subject, the light can be reflected under, rendering the background more tense, or on the subject proper, giving not only more illumination but illumination of greater uniformity Some subjects require a neutral ground. In this case the photographer will change his background many times during exposure He may start out for instance, with a pure white ground on top and remove grounds which are piled one on top of another until he passes through many shades, ending the exposure with probably a vivid red This changing of backgrounds during an exposure will often bring out an object that would have otherwise been flat

Cameras are manufactured especially for work of this nature and have scales of measurements so arranged that the ground glass support is part of the camera proper but movable either way with a thumb screw, so that an allowance can be made for objects of various thicknesses By attaching the support to the camera the camera can be swung or revolved during the exposure giving a uniform illumination to the subject. The camera may be supported by a tripod in a vertical position, as shown in the illustration When in the field the camera may be suspended from a tree limb

A stand, such as shown in the illustration, may be easily made and will answer all purposes admirably Any camera can be thus used with good results

A tilting tripod head which is simple in construction and inexpensive in cost, may be used in this style of photography to a good advantage In many cases most pleasing results have been secured by this simple device A sheet of glass for a background a tilting top for the tripod, and the outfit is complete

### INTERNAL COMBUSTION PUMP

(Concluded from page 257)

of the column of water cannot be suddenly arrested hence the pressure in C tends to fall below that of the atmosphere and the exhaust valve R opens as well as the water valves V Water rushes in through the water valves, mostly to follow the moving column in pipe D, but partly to rise in chamber C, in an effort to reach the same level within that chamber as in the suction tank When the kinetic energy of the moving column has expended itself by forcing water into the high level tank, it comes to rest, and, there being nothing to prevent a re-

turn flow, the column starts to move back toward the pump, and gains velocity in this movement until the water reaches the level of the exhaust valve, which it shuts by impact The result is that a certain quantity of burnt products of combustion becomes imprisoned in the cushion space $F$ and the energy of the moving column is expended in compressing this gas cushion to a greater pressure than that due to the static head of the water in the elevated tank $E\ T$ Consequently a second outward movement of the column of water takes place, and when the water reaches the level of valve $E$ the pressure in the space $F$ is once more atmospheric, and further movement of the water opens valve $A$ by suction against a light spring, and draws in a fresh gaseous charge If there were no friction the water would fall to the same level as that from which the last upward motion started, but the amount of combustible charge drawn in is slightly less than this movement would represent Once again the column of water returns under the elevated tank pressure and compresses the charge in the combustion chamber which is then ignited at the moment of maximum compression, and the same cycle of operations is repeated

The ignition is timed by a small apparatus somewhat resembling an ordinary engine indicator, which closes the electric ignition circuit at the point of maximum compression, an ordinary small battery, trembler coil, and sparking plug as are used in automobile practice

In starting the pump for the first time, compressed air is allowed to flow into the combustion chamber until the volume of air introduced is rather larger than the usual charge. The exhaust valve is then suddenly opened by means of a hand lever, and the escape of the compressed air permits a movement of the water column, which gives the cushion and suction strokes, and so draws in a fresh combustible charge, which, when the current is switched on and consequently fired, starts the pump working regularly When the pump is stopped in the usual way in regular work, it always stops with a fresh charge of explosive mixture present in the combustion chamber, so that it is only necessary to switch on the current and the pump is started up This enables the pump to be set in motion from the switchboard and without any preliminaries whatever

The pump has been severely tested, and is now in regular daily work at a large pumping installation in the Midlands, giving complete satisfaction The absence of all complicated gearing such as exists in the ordinary explosion motor is an outstanding feature, and guards the engine against breakdown, the only part that could fail being possibly a defective mushroom valve or spring Wear and tear is also reduced to an insignificant quantity, and the troubles incidental to lubrication are overcome

In its simplest form the apparatus converts gas power into hydraulic power, and may, therefore, be called a gas pump, but if the power is to be taken off a rotating shaft, the high pressure water is passed through a water turbine, and so back to the apparatus to be continually circulated The invention can also be applied with equal facility and efficiency for the compression of air

The pump has been elaborately described by the inventor in a paper published in the Scientific American Supplement

### RAPID TRANSIT BY BELT CONVEYOR.

(Continued from page 257)

with transverse shafts which carry the driving wheels of the platform The gradation in the rate of speed of the sections of the platform is secured by varying the diameter of these driving wheels, which are 8 inches in diameter for the 3-mile 16 inches in diameter for the 6-mile, and 24 inches in diameter for the 9-mile platform. The driving wheels are covered with rubber, as are the horizontal contact guide wheels, and consequently the motion of the platform will be both smooth and silent. The successive sections are coupled together by means of links 46 inches in length, and the coupling pins are placed at the center, from which the curves of the abutting ends of the platform sections are struck, consequently, the opening between the joints may be reduced to a minimum, and a smooth surface presented for walking, with no open spaces to bewilder or trip the passenger

The passenger-carrying capacity of the moving platform is just double the maximum capacity of the present Subway trains. According to the figures of the Public Service Commission, the total rush-hour capacity of the five-car local trains per hour is 22,500 and of the eight-car express traine 36,000, whereas the moving platform, according to their estimate, would carry 73,500 passengers per hour They state furthermore that for all distances less than four miles the moving platform is a quicker and more convenient mode of conveyance than the present local train service and even quicker than the local and express service combined, since a passenger may reach Times Square Station, from any local station south of Fourteenth Street (that is, supposing a moving platform were installed on a north and south avenue) quicker by the moving platform than by the local and express trains of the present Subway

In conclusion, however, we would sound a note of warning with regard to the possible interference of any moving platform subway that may be built with any future extensions of the present Subway In selecting the route, care should be taken to choose a location where the moving platform subway will not block any of the future through lines which must ultimately be built on practically every avenue in New York city.

### Why Are We Right-Handed?

(Concluded from page 261)

the lesion on the right side. The hand and arm centers in the brain are intimately linked in the cortex with the speech centers. And certainly Crichton Browne is correct in the inference that the preferential use of the right hand and arms in voluntary movements is due to the leading part taken by the left brain "We could not get rid of our right-handedness, try how we might, it is woven in the brain." And this, I believe, is the conclusion to which we must scientifically arrive "In the curious disease *aphasia*, in which one forgets words, the lesion lies in Broca's convolution, one cannot say cup, for example, though one sees a cup, but when the right hand touches the cup, the patient at once utters its name

Here one reflects In the process of evolution, did the heart tend to be on the left side, and the left brain tend to greater development, because the right hand came to be the most used? Or did the right hand come to be most used, because of these heart and left brain phenomena? I am, for my part, of the former opinion; the heart on the left side, and the greater left-brain development, are effect rather than cause, coming gradually to pass as man, in the struggle for the survival of the fittest, found right-handedness more and more advantageous.

Of course, there are professions and trades in which a certain amount of ambidexterity is essential. For example, the pianist, in playing the fugues of Bach, must produce with the left hand almost the same tones as does the right, and has to work a little harder too, for the bass notes of the piano are more thickly wired than the treble. A certain amount of ambidexterity is essential in the surgeon. Yet this gift has its disadvantages, withal; as when a colleague skilled in this way admitted to me that before doing a thing he wasted

... time in wondering which hand he should employ. But it is rarely really essential that such ambidexterity be acquired.

Finally, it may be objected, in favor of general education in ambidexterity Suppose one loses his arm, and that such an unfortunate be a clerk, who must earn his living by writing Such contingencies are almost as rare as the famous one by which Mrs. Brown justified to her husband her junk-shop purchase of a brass sign stamped "John Jones, Undertaker" "Our daughter will soon be of marriageable age, she *may* marry an undertaker whose name *may* be Jones, possibly John Jones, think how handy the sign will then be" In those rare cases of right handed mutilation there will in time follow, through education and practice, an adequate development of the right brain, just as if the unfortunate had been left-handed

## TREATMENT OF STEEL INGOTS.

(*Concluded from page 262*)

remains that by doing so Riemer has been able to demonstrate his success in pipe elimination on a considerable and commercial scale A large number of steel shafts, the steel for which was made by this process and with which the discard was kept at 10 per cent or less, have successfully passed the British Board of Trade requirements. Indeed, a reference to Fig 1 shows an ingot, treated by this method, in six transverse slabs on the right and left The slab shown on the upper left hand came from near the top of the ingot The longitudinal slab to the right of the center of the figure is from another ingot treated by the same hot-top procedure. The inconsiderable depth of the pipe seems pretty evident It extends perhaps 10 per cent of the total length But the actual percentage of steel involved is evidently much less than 10 per cent of the total

We have in Figs. 2 and 4 two views of the gas furnace There is an eye at the top which facilitates movement of the apparatus. Through two pipes—seen to advantage in Fig 4—the gas and air enter The air is under pressure In cases where it seems desirable to do so, the furnace may be employed as a means of heating the top of the mold preparatory to teeming the steel into it. The apparatus may then be let down until its lower edge is well inside the mouth of the mold, when the pouring of the steel may be performed without removal of the furnace There is thus ample opportunity to begin action without delay However, it is regarded as important to have not only prompt application, but an intense heat at once This requirement is met by preheating both gas and air In fact, heat may be applied in such intensity as to raise the temperature of the top of the ingot above the point of fusion It has been found unnecessary to prolong the treatment until solidification is completed. This is a favorable item, as thus the apparatus is released for other service, to which its portable character makes it applicable In Fig 4 the furnace is in operation heating the head of a 50-ton ingot. It will be understood that in this view the bulk of the mold is invisible The naked flames play upon the metal at the top of the ingot The preheating of the top of the mold tends not only to conserve the heat of the molten steels, but also to prevent heat loss by conduction from the gas flames. The furnace is being used in Fig. 2 for the purpose of preheating However, the ingot is, in this case, said to be present

Now in all procedure for the elimination of the pipe, we must not reach final conclusions as to their success without inquiring as to the segregation. The segregation is a locality where the steel has an excess of carbon, sulphur, phosphorus, etc., beyond the average contained in the ingot as a whole. Ordinarily, it should be removed. As it is usually located near the tail of the pipe, it may be disposed of by cropping the ingot a little below that point. However, it is well to investigate this question with some thorough ness, as the method of treatment itself may, conceivably, introduce variations from the rule Steel of uniform composition is wanted An ingot cast by the hot-top process was investigated as to its composition The average carbon content should have been 0 25 per cent By taking samples along the axis all but one were found to contain carbon in percentages running from 0 23 per cent to 0 25 per cent The exception was close under the tail of the pipe Its carbon percentage was 0 41 per cent. Similar results were found for sulphur and phosphorus. Thus they existed in the segregate in percentages about three and one-half or four times what they did below it.

## EGGS OF CURIOUS FORMS.

(*Continued from page 263*)

side the extinct Madagascar bird, the Epyornis, which measured more than thirty inches in its smallest circumference

The smallest birds' eggs are those of the minute species of humming birds, which are smaller than the eggs of certain kinds of tropical beetles But the common cuckoo lays the relatively smallest egg That is to say while the jackdaw and the cuckoo are about equal in size, the former's egg is five or six times larger than the latter's The fact that the cuckoo is wont to deposit its eggs in the nests of birds which are usually much smaller than itself doubtless accounts for this The relatively largest egg is laid by the kiwi, a strange wingless New Zealand bird The egg is no less than five inches long, although the extreme length of the bird itself is only twenty-seven inches.

Reptiles eggs are not very attractive objects. In the case of crocodiles and many kinds of tortoises they are pale-colored or white, and resemble those of birds in shape But the egg of the gopher tortoise is remarkable for its complete roundness. It might well be mistaken for a golf ball' Many snakes eggs are soft skinned, brown as to color, and look for all the world like a number of new potatoes.

The eggs of fishes are usually small, soft, and inconspicuous The most remarkable point about them is the extraordinary number laid by the individual A single cod for example lays as many as nine million eggs But a striking exception to this piscine rule of numerous inconspicuous eggs is seen among the sharks and their allies These "tigers of the sea" lay eggs which are large in size, few as to numbers, and deposited singly instead of in masses These eggs, of which several examples are shown in the accompanying photos, are known to fisherfolk by such names as "pixy purses" "fairy purses," or "mermaid's purses." They consist of a dark-colored, leathery envelope, and are usually adorned with frills, horns, or long twisted tendrils These appendages serve the purpose of keeping the egg case supported among the branches of seaweeds, thus preserving the embryo from the damage it would sustain were the "purse" carried hither and thither by the waves

Amphibians—frogs newts, and the like—lay fish-like eggs without exception The Surinam toad, however, has a remarkable way of dealing with the eggs when they are laid The male takes the eggs one by one, and imbeds them in the soft skin of the female's back, each egg in a separate cell Here the eggs remain being carried about by the female until the young toads hatch There may be as many as one hundred and twenty cells in the back of a single individual although from sixty to seventy is the more common number

The egg laying habits of the "midwife" frog of Europe are almost equally curious The eggs are deposited by the female in the form of long chains which may be upward of a yard and a half in length These chains are taken by the male and wound around his legs and

(*Concluded on page 270*)

(Concluded from page 269.)

thighs. Thus equipped, he retires to a hole in the bank of the stream, where he remains in concealment until the tadpoles are on the point of hatching. Then he enters the water, when his off-spring emerge from the eggs, and wriggle away to take care of themselves.

On the seashore, after rough weather, may often be seen an object which bears no small resemblance to a cluster of purple grapes. This is a mass of cuttle-fish eggs—that strange, eight-armed mollusk which disports itself in the waves to the undoing of such marine creatures as are unlucky enough to come within grasp of its suckers. Each "sea grape" is produced with a flexible stalk, by means of which it is joined to its fellows, the whole mass being fixed to some stationary object, such as a rock or stone. But like the eggs of so many marine creatures, the eggs of the cuttle are at the mercy of the elements, and in times of tempest they are often torn from their moorings, and cast bruised or broken upon the shore.

Near relatives of the cuttle are snails and shellfish of many kinds, and among this great group of animals' eggs so many strange forms are found that a description of them would fill a bulky volume. Many of the large land snails produce hard-shelled eggs, differing little in appearance from those of birds. An example is the West Indian *Bulimus*, shown in the annexed photograph, together with its white, elongated egg. But the egg cluster of the common whelk (*Buccinum*) is like a rather dingy honeycomb, partially squeezed between the hands. When the eggs are alive and healthy, the form of the young whelks can plainly be seen through the semi-transparent substance which envelops them. Another quaint form of molluscan egg is that produced by the turret shellfish (*Turretella*). The eggs are joined together like a number of small beads on a flexible cord.

If the eggs of mollusks are varied in appearance, the eggs of insects are infinitely more so. Moreover, many of them are marvelously beautiful in form and embellishment. This beauty is almost always hidden from the eye unaided by the microscope, for the eggs of most insects are mere specks, often less bulky than a grain of sand. Who, for instance, would expect to find beauty in the egg of the house fly? Yet place several of these eggs beneath a powerful lens, and a vision of beauty greets the eye. The eggs of many butterflies and moths—mere atoms laid upon a leaf—are equally attractive. In point of beauty, the egg of the moth or fly ranks far above that of the ostrich. One ponders upon this strange problem without gaining enlightenment. Why this delicate lacework? Why this flower-like elegance? Above all, why adorn at all objects of such extreme minuteness? The smaller the object, the greater the care Nature seems to lavish upon it. An example of the fact is found in the case of eggs laid by the minute insects which spend their whole lives among the feathers of birds. These minute beings pass under the unsavory title of "lice." Yet their eggs, when magnified, exhibit an amusing diversity of form and a beauty quite fairy-like. They are among the most popular of microscopic objects.

In conclusion it may be said that certain insects deposit their eggs in clusters which bear no little resemblance to nuts or fruit. Such is the case with the "rear-horses" (*Mantidæ*) and their allies. Possibly this resemblance may be of importance in protecting these eggs from the attacks of insectivorous birds and other creatures.

### Comets Expected in 1910.

The present year promises to be particularly rich in comets. Four comets, those of Winnecke, Daniel, Halley, and Innes, have been or are already visible. Innes's comet, which was very bright, appeared suddenly, it will be recalled, in the midst of a recent auroral display at Johannesburg. In addition to these four, seven periodic comets are expected to return in 1910. Probably not all of these comets will be visible, because some will be unfavorably situated with respect to the sun at the time of perihelion passage. The expected comets are the following: 1 Giacobini's comet, 1896 V. It was first thought that this comet would reach its perihelion about the middle of February, but later calculations have proved that it really passed its perihelion last December. It has not yet been seen and, as its position is very unfavorable, it may escape observation altogether. 2 Swift's comet, 1895 II. This comet was not seen at its return in 1902, and unless its orbit has been considerably changed, the conditions for its observation will be still less favorable this year. It should have passed its perihelion about the end of Jaunary, and should then have been almost exactly behind the sun. 3 The second periodic comet of Tempel should reach its perihelion about February 21st unless its orbit has been greatly changed since 1904, when the comet was last seen. The conditions for observing this comet in its perihelion passage this year are, however, very unfavorable as, like Swift's comet, it is almost behind the sun. 4. D'Arrest's comet was seen for the first time in 1897, it was expected to return in 1904, but was not observed, owing to unfavorable conditions. This year, if its orbit is not changed, it will reach its perihelion in October. Its position then will be very favorable for observation, so that this comet will probably be visible next summer. 5 Spitaler's comet, 1890 VII, escaped detection at its visits in 1897 and 1903, because of poor conditions for observation. Dr. Hopfer, of Trieste, has shown that the orbit of this comet has been greatly altered by perturbations caused by the influence of Jupiter between 1890 and 1903. In consequence of these perturbations, the periodic time of the comet has been increased from 6.42 years to 6.82 years. The comet should pass its perihelion in October, 1910, in conditions favorable to its rediscovery. 6 Faye's comet is also expected to return in the latter part of October in conditions favorable for observation. 7 Brooks's comet, 1889 V, is expected to reach its perihelion in the summer of 1911 but it will probably be discovered during the coming summer.

### Moving Picture Royalties.

The moving-picture industry is on a distinctly theatrical basis. It has its "trust," its theaters where actors play before a camera, its scene shifters, its supernumeraries, its property men, and a whole theatrical staff more or less similar to that of the regular theater. The "trust" in question was formed about a year ago by a number of manufacturers of films under the title of the Motion Pictures Patents Company. Patents, chiefly those of Thomas A. Edison, were pooled, and active steps were taken to purge the moving picture theater of some of the more objectionable pictures which have brought down a hail of criticism upon the industry, to license the moving-picture theater to use the apparatus and exhibit pictures, and to control the industry in general. There were many independent manufacturers who refused to pay royalties or to acknowledge the patent rights of the Motion Pictures Patents Company. A suit was recently brought by the company against Carl Laemmle, a well-known manufacturer, and the Independent Moving Picture Company of America, of which he is president, as well as the Pantograph Company, to restrain the alleged further infringement of Edison patents controlled by the Motion Pictures Patents Company. Inasmuch as the patents in question had already been adjudicated and their validity upheld, an injunction was granted. The hearing brought out some very interesting statistics, which will undoubtedly open the eyes of the general public.

(Concluded on page 272.)

(Concluded from page 270)

lic. It seems that every day some four or five million persons attend the thirteen thousand moving picture shows of the United States. The pictures which flicker on the screen before the spectators are projected by means of apparatus, the basic patents of which were taken out by Thomas A Edison These four or five million persons, therefore, unwittingly pay royalty to Mr Edison whenever they hand in their nickels or their dimes at the box office It is stated that about 1,440,000 feet of film are made by the members of the Motion Pictures Patents Company On this production a royalty of half a cent per foot is paid to Mr Edison, so that his revenue from the moving picture-loving public amounts to $7,200 per week

The action was brought by the Motion Pictures Patents Company to restrain infringement, but the defense set up was that the company violated the Sherman anti trust law The decision handed down by Judge Noyes of the United States Circuit Court was that the question at issue was patent infringement and not violation of the anti trust law, for which reason he granted the injunction

### The Brennan Mono-rail Car.

A successful demonstration was given recently at New Brompton, of the Brennan mono-rail car At the trial an 80-horse power generating set was working The trials commenced with running the vehicle loaded with packing-cases, round the circular track of 105 feet radius at a speed approaching 20 miles an hour The stability of the car under these conditions was apparently all that could be wished, the vehicle canting over several degrees toward the center of the circle of track This demonstration was followed by an exhibition of the facilities afforded by such a car for unloading The vehicle was intentionally tilted over on to chocks on the right-hand side and some cases unloaded It was then righted and then tilted over toward the left side and other cases unloaded, being finally righted again, all these operations of tilting and righting being performed solely with the assistance of the gyroscopic gear The next trial consisted in carrying passengers round the circular track About fifty passengers were taken at a time, and several complete circuits of the one-eighth of a mile track were made with each load During these runs we timed several rounds at speeds of between 18 and 20 miles an hour The motion on board was quite pleasant the vehicle riding very well The inward cant that the vehicle acquires when traveling on curves at high speed naturally added to rather than detracted from, the comfort of the passengers Altogether some 300 persons had an opportunity of being on the carriages under these novel conditions The demonstration which followed showed the ability of the vehicle to take sharp curves, this, however, revealing nothing more than was evident from the earlier trial toward the close of last year The carriage, with passengers on board, was then run backward and forward at as high a speed as was practicable along the straight with perfect success The slight lateral swaying under these conditions was quite easy, and free from jerks and jolts, and not at all unpleasant. The oscillation is of very small amplitude, as the controlling action of the gyroscopes quickly damps out any tendency to a larger movement.—Engineering (London).

A compound of six parts lard and one part rosin is given by the Brass World as an efficient protection for polished steelwork from rust. The two in- the mass from becoming rancid, and stirred until cold The rosin prevents the mass from becoming rancid and also acts as an air-tight film If rubbed upon a polished steel surface it effectually preserves and protects the polish.

REMINDER BULLETIN

## A Boon to the Busy Man

The use of the most modern type of speed-making locomotives, coupled up to the best type of equipment and guided by the most vigilant management makes railroad travel secure and prompt

The time of a busy man is one of his assets It means either gain or loss to him.

The certainty of figuring his time in transit to the exact hour relieves his engagement list from entanglement.

The telephone may make the engagement, the train will keep it.

**The Pennsylvania Special** follows up the telephone message. It brings the two ends of the wire together and consummates the meeting between working hours

The man with business connections in New York and Chicago can lose no time by traveling on the **Pennsylvania Special.** It runs while the desks are closed.

**Pennsylvania Special** (18 hours between New York and Chicago) leaves New York 3 55 p. m Downtown Tube 4 05 p m. and arrives Chicago 8 55 a m

Over five hours for business to 2 45 p m when it leaves Chicago for the East and arrives in New York next morning (Breakfast on the train) at 9 45 a m

The side walls, 8000 feet long, are built in sections between plate steel forms. To the right of the completed wall is seen the interior face of a steel form with the form for the end of the section upon which the men are at work extending transversely. In the pocket thus formed the men are shoveling and tamping the wet concrete.

BUILDING THE HUGE WALLS, 50 FEET THICK AND 81 FEET HIGH, OF THE GATUN LOCKS AT PANAMA.—[See page 279.]

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## THE PANAMA CANAL AS AN INVESTMENT

CONSIDERABLE doubt is being expressed just now as to whether the Panama Canal will prove to be commercially a paying investment, and in a series of articles, which have recently been published, Admiral Evans, proceeding along several rather formidable lines of argument, is apt to leave, at the first reading, a depressing conviction that this great national undertaking can never be self-supporting.

On the other hand, there is the fact that other great canals, such as that at Suez and the one which has made Manchester a seaport, were, during their construction, the subject of similar dismal forebodings. Yet Suez has proved to be one of the most profitable commercial undertakings in the history of the world, and the Manchester enterprise, in spite of the few lean years of its earlier operation, is now accomplishing all and more than was promised.

It is well to remember, moreover, that the admiral's pessimistic view of the future is based upon a comparison of the sailing distances between certain trade centers via the two canals, and he assumes that unless the distances via Panama are shorter than those over the present routes, the new waterway will be powerless to divert existing trade from its present lines of sailing. Now although the principle as here laid down is broadly correct, it should not be forgotten that the connecting of the two great oceans is certain to materially affect the trade conditions along the whole stretch of both the Atlantic and Pacific seaboards of North and South America. Indeed, the cutting of the canal may so enlarge the trade and importance of certain of the maritime cities as to render it expedient for shipping which at present uses the Suez Canal route to take the longer route by way of the Panama Canal.

But we should judge of the value of the Panama Canal rather from the military than the commercial point of view—a fact which is well understood at Washington, where undoubtedly it acted as the compelling motive in urging Congress to undertake this stupendous work. That 14,000-mile trip of the battleship "Oregon" during the Spanish war was an object lesson, the significance of which has never been forgotten. The opening of the canal will render the whole naval force of the United States available in either ocean. In its ability to strike a rapid and decisive blow at any threatened point along the whole of the United States seaboard, the efficiency of our fleet will be practically doubled, and the fact that the whole navy can in a few weeks' time be assembled in the Pacific Ocean will enormously increase the naval prestige of the United States in the Orient, and must inevitably tend to preserve the peace in those great Oriental questions which begin to loom so large on the diplomatic horizon. So long as the Isthmus of Panama exists as a barrier between the Atlantic and the Pacific, we must build at least three battleships where otherwise we would build two, and the first cost of construction and the heavy cost of maintenance and operation will far exceed any temporary or even permanent deficit which may develop in the operation of the canal as a commercial venture.

Meanwhile, under the administration of that most efficient body, the Corps of Engineers of the United States Army, the execution of the work is proceeding with a rapidity which is in pleasing contrast to the confusion and disappointment which marked the earlier years of American occupancy; and in the series of striking illustrations of the work which we present in the present issue, we are enabled to give our readers an adequate impression of the magnitude and solidity of the permanent works, the most monumental concrete structures ever attempted.

## RELATIVE REPAIRS ON NAVY-BUILT AND CONTRACT-BUILT SHIPS.

THE wisdom of the policy of building at least a small portion of the new ships of the navy at our leading navy yards has been and is yet a question upon which there is much division of opinion. The principal argument in favor of this policy is that it becomes possible to maintain an adequate force of skilled mechanics permanently at the yards, and avoids that disastrous breaking up of the organization and scattering of forces which occurs in the slack season when the annual repairs upon the ships are completed and they have sailed for the summer maneuvers. The maintenance of a permanent force increases efficiency and insures that the leading yards will be in a position to meet at once the heavy strain which would be thrown upon them in the event of sudden hostilities. Of equal importance to the question of the effect of new construction in maintaining a permanent force in the navy yards is that of the character of the work that they can turn out. Conclusive data upon this subject are furnished by those two sister ships, the "Connecticut" and the "Louisiana," the first built at the New York navy yard, and the latter by the Newport News Shipbuilding Company. If certain disabilities under which the navy-built ship labored, due to slowness in the delivery of armor and the fact that she required special fittings as a flagship be considered, the time and cost of construction may be regarded as approximately the same as those of the ship built by contract.

As to the question of the relative quality of the work done, there is no surer test of this than the amount of repairs which have been made upon each vessel in the four years that they have been in commission. The following figures, taken from the report of the Paymaster-General of the Navy, are very conclusive on this point. In 1906, their first year of service, the repairs on the "Connecticut" cost $236.97, and on the "Louisiana" $5,851.09. In 1907 the repairs on the "Connecticut" amounted to $53,557.47, and on the "Louisiana" to $99,851.09, and the totals up to the end of the fiscal year 1909 were, for the navy-built ship $111,833.58 and for the contract-built vessel, $149,167.

In view of the fact that during these four years the cost of the repairs for the "Connecticut" was about 41 per cent less than that of the "Louisiana," what becomes of the oft-repeated statement that our navy yards are incapable of turning out work of the same high quality as that of our private yards?

## THE NEED OF AN IMPROVED PARCELS POST

THE existing restricted parcels post system of the United States Post Office, as established by Congress in 1874, has so far limited the easy exchange of commodities and merchandise between manufacturers and consumers that it is making the United States appear to be wonderfully behind the times as compared with some foreign nations, such, for instance, as England, France, and Germany. It is a fact to-day that an American in England can send home by mail to any part of the United States a parcel weighing two and one-half times more than the United States limit for about one-third less in cost than the present home rates. In other words, the world postal union package unit is eleven pounds to the parcel at the rate of twelve cents per pound. Whereas the United States unit is only four pounds to the package at a cost of sixteen cents to the pound. The parcel rate in the United States prior to and early in 1874 was eight cents per pound for a package limited to a weight of four pounds. After that the rate was doubled, but the weight remained the same. Since 1874 the cost of transportation has greatly decreased. The question is, why should not the public through its representatives in Congress be given the benefit of this decrease by the establishment of a uniform low postal rate for parcels that will encourage the use of the Post Office as a medium of exchange of commodities, and thus greatly facilitate trade?

Since the experimental introduction of the Rural Free Delivery system in this country, its operation has proved so great a necessity, convenience and success that Congress overlooks the annual deficit arising from the unreasonable restriction placed in the law limiting the kind of postal matter to be carried to letters, newspapers, and periodicals. The weight of this average load is ascertained to be but twenty-five pounds per trip, while the vehicle which the postal agent is required to supply can readily carry two hundred pounds. It is estimated that should the restriction be removed and parcels be carried, even allowing only one or two parcels per trip, enough revenue would be received from the additional postage to more than pay the total cost of this system, and make it self-supporting.

A movement in this direction is the introduction of a bill before Congress, prepared by the Postal Progress League, known as the Bennett Rural Parcel Post Bill, now in the House Postal Committee, which provides for very moderate postal local rates along [illegible] routes between the city or town and places in [illegible] country. It would enable the merchants [illegible] commercial center to send, say on telephone [illegible] small supplies directly to the purchaser living on the route, and would promote the exchange of merchandise between the residents themselves on the route, as well as their sending products to the commercial center. the service would be somewhat similar to that of the usual postal railway coach and its collection and distribution of mail matter.

With the extension of good roads and the use of rapid automobiles, a longer route could be established than now exists, as a maximum distance, which would reduce the number of vehicles required and economize the cost of maintenance.

In this connection the experience of the use of the mail automobiles in London is worthy of note. At the second annual dinner of the Royal Automobile and Associated Clubs of London in the summer of 1909, Sir Henry Norman in a speech alluded to the success of the mail automobile as a time and money saver in the transportation of mails, by saying that in the city there were thirteen local motor services averaging thirty-two miles a day. There were also ten sets of services in and out three times a day between London and the principal towns on the outskirts of the city. In the thirteen long-distance night automobile mail coach services a saving of $300,000 a year was affected as compared with the horse service which did the same work only a few months before. The London Post Office is now operating no less than sixty of these motor services.

Results of this character certainly show that the establishment of a very low postal rate for parcels is feasible, since it will create more than sufficient revenue to pay the cost, besides saving money for the merchant and consumer.

It is to be hoped that Congress will give such intelligent consideration to all matters relating to postal improvement that the system, so useful and necessary to the people, will forthwith be placed upon a sound business basis.

## HYDRAULIC TURBINE REDUCTION GEAR.

IN the issue of the SCIENTIFIC AMERICAN of February 12th of the present year, we described the turbine reduction gear designed by McFarland and McAlpine, in which a mechanical gearing is interposed on the shafting between the turbine and the propeller, for the purpose of reducing the economical high speed of the former to the relatively low economical speed of the latter, and it was noted that a mechanical efficiency of 98.5 per cent had been secured in the shop tests. Simultaneously with the development of this gear, the problem was attacked by Dr. H. Föttinger, who, with the assistance of the Vulcan Works at Stettin, has produced a reduction gear which substitutes for the toothed gear of the McFarland system a set of hydraulic turbines through which a body of water is kept in constant circulation, and by the proper proportioning of whose buckets and channel ways the desired reduction of speed is secured. A complete description of this gear with illustrations is given in the current issue of the SUPPLEMENT, to which reference is made for fuller details than are here given. The turbine shaft and propeller shaft are independent. Upon the former is mounted a rotary pump, which delivers its water into the buckets of a water wheel which is mounted rigidly upon the propeller shaft, and it will be evident that by selecting the proper relative dimensions of the two members, the desired ratio of speed between turbine and propeller can be obtained. In its simplest form the reduction gear consists of a pump, guide channels, and a driven water wheel, but in the larger powers one or more intermediate wheels would be interposed between the pump and the driven wheel, indeed transformers with one or more stages are preferable when a considerable reduction of speed is desired. With a reduction ratio of between 1 to 4 and 1 to 6, using two reduction stages, an efficiency of from 80 to 82 per cent is secured. This seems low when compared with the 98.5 per cent efficiency of the McFarland gear, but the German system has the advantage that it is readily reversible. The system has been tried on a small vessel of 76.7 tons, which has been driven by a 500-horse-power turbine at a speed of between 12 and 13 knots. When the reversing lever was thrown over at full speed, the propeller shaft came to a standstill in 5 seconds, and within 15 seconds had acquired a reversed speed of between 200 and 250 revolutions. On the whole, it would seem that the German, because of its low efficiency, cannot compete with the American system on ships that make long continuous voyages. On channel and river steamers and for tugs and small vessels it has some advantages.

**Asbestine, for Fireproof Coatings.**—Prepare a paste-like mass of asbestos, powdered silica, caustic potash, and soda-water glass. To be burned and sand mixed with it.

## ENGINEERING.

[illegible]-atlantic record has been broken, this time by the "Mauretania," which reduced the long Atlantic course of 2,889 miles by 26 minutes, making the passage from Daunt's Rock to the Ambrose Channel Lightship in 4 days, 15 hours, and 29 minutes, at an average speed of 25 91 knots.

[illegible] value of the steel car as a protection to passengers in the event of collision was demonstrated in the recent clash of two trains in tha Hudson tunnels. There was no such telescoping as wonld probably have occurred with wooden cars, and the injuries were merely such as resulted from the passengers being thrown down by the shock of the collision.

A recent issue of Cassier's, states editorially that the first British steamboat was not Bell's "Comet," which ran on the Clyda in 1811, but the "Accommodation," which commenced running between Quebec and Montreal on the St. Lawrence River on November 5th, 1809, or two years after the "Clermont" made her [illegible] run from New York to Albany The first steamers on tha Lakes were tha "Ontario" and the "Frontenac," which appeared in 1816

A French naval constrnctor, basing his deductions on the recent French maneuvers, believes that the future submarine will be a "submersible destroyer" of 20 knots surface and 15 knots submerged speed, of sufficient radius of action to accompany the main fleet on long cruises. He believes that the greater the radius of action and tho higher the submerged speed, the nearer will such a vessel approximate a perfect underwater instrument of offense and defense

Some tests of the effect of superheating recently made on the American yacht "Idalia' show striking results. When nsing saturated steam, the consumption of water per indicated horse-power was 18 3 pounds. This was reduced to 17 pounds, with 57 degrees of superheat, 15 8 pounds, with 96 degrees, and to 15.5 pounds, with steam at 105 degrees superheat, this last being a saving of 15 3 per cent of steam, a truly remarkahle showing The trial with saturated steam was of two and one-quarter hours duration, and with 105 degrees the test lasted for three hours.

A report of tha Puhlic Service Commission, relating to the delays of passenger trains in New York State during December, shows that 60,385 trains were run, of which 75 per cent were on time at division terminals. The average delay for each train was 39 7 minutes, and the proportional causes of delay were Waiting for trains on other divisions, 40 9 per cent, waiting for train connections with other roads, 14 4 per cent, train work at stations, 12 2 per cent, trains ahead, 8 per cent, meeting and passing trains, 4 8 per cent, engine failures, 4 3 per cent, train wrecks, 3 8 per cent.

An experiment which is being tried on the Hudson and Manhattan Railroad tunnel system beneath the Hudson River will be watched with much interest by both the railroads and the puhlic It consists in illuminated station signs, placed inside the cars, which are so arranged that the guard by pressing a hutton when the train starts, rings a bell and causes the sign to display the name of the next station This sign continues to be displayed until the train leaves the station designated A simple device this, whose utility is so obvious, that it should have been in use from the very commencement of electrically-operated rapid transit.

A commission of engineers and scientists is making an exhaustive study of the causes of the recent flood in Paris, preparatory to devising a system of protective works which will absolutely prevent any recurrence of the disaster The main work of the commission will be to devise a plan for keeping the river Seine within its banks either by the construction of higher embankments or by the provision of a by-pass channel to carry the surplus waters around the city At the same time the commission will investigate the various public services, including surface and subway lines and the sewer, gas, electricity telegraph, and telephone systems which were affected hy the inundation, with the object of remedying the defects which were daveloped during the flood

The work of providing adequate coast fortifications has been carried to the point at which they may now be considered to be very complete, at least as far as the guns and emplacements are concerned. The full efficiency of these fortifications cannot be realized, however, because of the lack of proper submarine mine equipment and the proper accessories for the mines and guns already installed, such as fire control apparatus, searchlights, power plants, and adequate ammunition. The Chief of Coast Artillery says "Without these accessories the $70,000,000 already expended would be wasted, since the guns would be of no more value in the defense of the forts in which they are mounted than so many dummies." To make this provision will require about $15,000,000.

## ELECTRICITY.

As the Glidden tour this year will pass through territory where the telephone and telegraph service is very poor, it has been decided to equip the cars with wireless telegraph apparatus. This will make it possible to keep in close touch with the contestants, and the latter will be able to report accidents and call for help when necessary

In plants which use a gas engine to drive their generators the variations in speed of the engines are not noticeable if carbon filament lamps are used, because the filament is quite thic't and does not respond quickly enough to show any fluctuations in light With tungsten filaments the light waverings are very annoying, and gas-engine manufacturers have found it necessary to equip their engines with heavier flywheels

A convenient method of determining variations in the candle-power of a lamp was described in a recent number of Elektrotechnische Zeitschrift. A selenium cell is employed, which is exposed to the lamp under test and is placed in series with a recording milliammeter The curve recorded by the milliammeter, which is due to the variable resistances of the selenium cell, indicates the variation of the candle-power of the lamp To be sure, this does not give an accurate photometric measurement.

A large section of land has been bought by the Commonwealth Edison Company in the northwestern part of Chicago, where two large generating stations are to be built Each station will be equipped with six turbines and in the first station the capacity of each turbine will be 30 000 horse-power It is expected that within two years 60,000 horse-power will be in operation These stations are made necessary by the fact that the output of the company has doubled every three years for the last twelve years

Chicago is trying a new car designed to remove city garbage over the street railways at night The car is of steel construction, 34 feet long divided into three sections which are so shaped that they can be dumped with a pole by a single man thus doing away with the necessity of using air cylinders or other mechanical dumping apparatus The sections are made watertight, so that there will be no leakage of wet garbage The car is not provided with motors It is intended to use the car in the daytime for hauling concrete and construction materials

A novel method of recovering a sunken cargo has been adopted by the United States Steel Company A large magnet, 3½ feet in diameter and weighing 3 000 pounds, has been employed in raising kegs of nails from a barge that was sunk in the Mississippi River near New Orleans The magnet raised five or six kegs at a time, or about a ton at each lift The advantage of this method was that it avoided breaking open the kegs as would have been the case had a dredge been used The magnet is soon to be used for raising a sunken load of woven wire, and also for a load of steel baling strips

Several years ago the Illinois traction system decided to use sleeping cars between Springfield and East St Louis As this system has proved a success, several more cars have been ordered for use between St. Louis and Peoria. These cars will differ from the first ones in having no motor equipment They will be trailers and it is expected that a good deal of the annoying vibration of the first cars will thus be overcome The cars will be 54 feet long and will be provided with ten upper and ten lower berths It is believed that this system may compete with through steam railroad service, for the reason that at night one does not care how fast he travels provided he can sleep comfortably and find himself at his destination when he wakes up in the morning

The following subjects will be taken up at the International Congress of Telephone and Telegraph Engineers, which is to meet at Paris this year (1) Manual versus automatic systems of telephone working (2) (a) Simplification of telephone circuits, (b) selection of frequency and secondary potential (for purposes of theoretical investigation) with a view to facilitating the approach of the telephone current to the sine wave-form, (c) the circumstances conditioning the adaptability of telephone apparatus to the lines, induction coils, microphone resistance, etc (3) Precautions to be taken for the avoidance of mutual disturbance in the case of power circuits running in close proximity to telegraph and telephone lines. (4) Telephony between places at great distances from each other Construction of cables for long-distance use relays, combination of aerial lines with cables. (5) Wooden poles—new process for impregnation and preservation—and procedure described from actual practice as to staying and strutting. (6) Party lines and selective calling upon telegraph and telephone lines. (7) Telegraph systems for heavy traffic Multiple type-printing telegraphs and the Mercadier system.

## SCIENCE.

**Mr. H. H. Clayton**, late of the Blue Hill Observatory, has gone to Buenos Ayres to organize kite and balloon observations under the direction of the Argentine Meteorological Service

**Knut Angström**, professor of physics at the University of Upsala, died March 4th He was distinguished as an investigator of solar radiation, and devised the instrument adopted by international agreement as the standard for measuring this element, viz., the Angström electric compensation pyrheliometer

**The International** Meteorological Committee, which assembles triennially, will hold its next sessions in Berlin during the last week of September 1910 Dr W N Shaw, director of the British Meteorological Office, is president of the committee and Prof Dr G Hellmann, director of the Royal Prussian Meteorological Institute secretary

**The standard** troy pound of the Philadelphia Mint was recently tested by the Bureau of Standards and found to be slightly over weight, because of the accumulation of oxide on the surface The test was certified to by the bureau officials in a report to the Director of the Mint It was shown that when the weighing took place the temperature of the air was 22 deg C, the relative humidity was 60 per cent, the barometer was 754 millimeters the mean density of standards was 8 42 at 22 deg C The weight variation of the troy pound was determined to be 0 007 of a grain This variation is what is called by scientists "tolerance,' and is negligible In the coining of $100,000,000 the government would lose just $121 53 as a result of the slight overweight

**The Flora** bust controversy will not die Dr George Pinkus the well-known German chemist analyzed the wax in the famous bust and found it to be a combination of fat, spermaceti and beeswax Alleging that spermaceti was unknown until 1700, he argues that the bust could not have been Da Vinci's Furthermore, he proved that the composition is identical with that used by Lucas the sculptor who is said to have made the bust Dr Bode still maintains that the bust is a genuine Da Vinci He replies that Prof Rathgen made several analyses and found that the wax of the bust was different from that used by Lucas In Dr Bode's opinion Dr Pinkus analyzed only part of the outer layer of the wax which Lucas added Moreover, Dr Bode quotes Prof Lippmann of Halle University as authority for the statement that the peculiar wax in the bust was abundantly employed in Mediterranean countries at the beginning of the sixteenth century despite the belief in some quarters that it was not known until 1700

**At the** invitation of the Rochester Chamber of Commerce and the Civic Improvement Committee of that city the conference of 1910 will be held at Rochester May 2nd to 4th American cities are being aroused to the necessity for a city plan, and for the prevention of congestion of population Many cities have plans others are getting them a few are following them out Why it is imperative to adopt a city plan is becoming secondary in practical importance to how the city plan once adopted can best be carried out. The purpose of the conference this year is not primarily to continue the campaign of education nor to increase the literature which makes up the already weighty argument for the necessity of planning American cities but the conference is a gathering of experts called because of their intimate knowledge of a specific subject to make a concrete contribution to the science of city planning Generalities will be most carefully avoided The aim will be to discuss phases of each selected subject thoroughly rather than to wander through the whole field

**Prof. Pierre Roveda**, an architect of Buenos Ayres has devised a special plan for the construction of whole districts of houses for the working classes Instead of employing the usual square block as a unit, Prof Roveda adopts a circle varying in diameter from 100 to 130 yards This circle of ground is subdivided into 99 radial lots converging to a center The circle is concentrically divided to form an interior avenue four yards broad to permit of communication with the center of the circle Each avenue leads to external sidewalks and to longitudinal and transverse streets In the center of the circle is a plot of 40 yards in diameter where children may be left to themselves without their parents' care, in charge of a specially designated person In this garden a playroom a school, a hospital, a fire station, and an administration room are to be found Naturally this circular plot of ground will leave four corners free In each of these corners Prof Roveda intends to erect four chalets, such as grocery shops dairies haberdashers and the like, which are to be conducted on a co-operative plan In each of the 99 radial plots a workingman's house is to be built on the English plan. It is argued that the circular arrangement will give continuous sunshine at all hours of the day and plenty of light and air.

# A NEW TYPE OF TORPEDO BOAT

## A DOUBLE-HULLED BOAT WITH ITS ENGINES ENTIRELY BELOW THE WATERLINE

A new type of war vessel provided for by Congress in the Naval Appropriation Act of last year will be officially tested by the United States government at Boston within a few days. It is known as the subsurface torpedo boat and is designed to be immune from the small gun fire now relied upon as a protection against ordinary torpedo boats. It consists of a submarine hull which contains all the machinery and torpedo armament suspended from an unsinkable surface hull divided into compartments packed with cellulose. Last year's law authorizes the purchase of this boat when the official trial shows that it fills requirements and the construction under contract of two others of the same type. The boat has had a preliminary trial. Tams Lemoine & Crane, the consulting architects, report that it easily made 18 knots an hour, thus exceeding the required speed by 2 knots.

Six tons is the weight of the vessel and its length is 46 feet. The price which the government has agreed to pay is $22 500. The small subsurface boats can either be used for coast defense or they can be carried on board of the larger vessels in an armored fleet. In time of action they can be launched and directed by day or night against the enemy's fleet, particularly for operations against ships lying under the protection of land fortifications or mine fields, where expensive battleships should not be risked as they were at Manila, Santiago and Port Arthur.

In the submarine hull of the new style boat is an eight-cylinder gasoline engine of 150 horse-power. The explosive charge carried for use on hostile vessels is 1 000 pounds of guncotton. An armored conning tower on the surface hull communicating with the submarine hull enables the navigator to direct and control the boat's movements. Only two men are required on board.

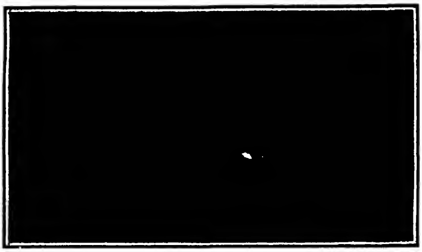
It is estimated that a fleet of fifty of these subsurface torpedo boats will cost about as much as two or three destroyers or submarines. As their cruising radius is 200 miles their principal function will probably be for the defense of ports and unguarded coast line.

The subsurface boat is to be operated in one of two ways. Either it may be steered within short torpedo range and aimed at its objective, the crew leaving it in lifeboats or buoys, or it may be fitted with a submerged bow torpedo tube to discharge the ordinary 18-inch torpedo.

For the firing of the high explosive use is made of an electrical firing circuit which is actuated by a bow firing pin but which is kept open and safe by a switch in the conning tower until the boat is deserted. It is also proposed to continue the firing circuit around the inner skin of the upper hull below the water line so as to explode the charge if the boat should be rammed, and thus deter hostile boats from ramming. Also it is proposed to use on the engine sparking circuit a time switch which will automatically break the sparking circuit and stop the engine and boat if it misses its objective.

The total government appropriation for boats of this type is $445 000. When the first is approved the Navy Department is authorized to contract for two others, one more of the same size and one larger and faster—a $400 000 subsurface seagoing destroyer.

A year or two ago the Assistant Secretary of the Navy recommended the building of a number of small motor torpedo boats of approximately the same size as this to be laid up on shore in peace time for occasional practice runs by the naval reserve and for use by them in case of hostilities. The boats proposed were to be of 17½ knots speed which is somewhat less than has been achieved by the present subsurface boat on its preliminary trials.



THE SUBSURFACE TORPEDO BOAT ON ITS TRIAL TRIP

The English motor torpedo boats built by Yarrow with Napier engines make about 18 knots. They are of about the same size as the vessel we are describing and are used for the same purposes. It would appear therefore that no speed has been lost by carrying the engines and torpedo below instead of within the hull of the boat. It is suggested that in view of the comparatively small expense several flotillas of these boats could be distributed along our coasts and laid up with the engines greased, in which condition the expenses of maintenance would be very small.

There can be no doubt that all the navies of the world are just now directing special attention to subsurface warfare and the trials of this boat, which offers some decidedly valuable features in the great protection afforded both to the motive power and the high explosive, will be watched with no little interest.

The general design of this very interesting craft is due to Clarence L. Burger, C.E., of New York and the plans, calculations, etc. were made by the Naval Architects Tams, Lemoine & Crane.

### The Oldest Attic Letter

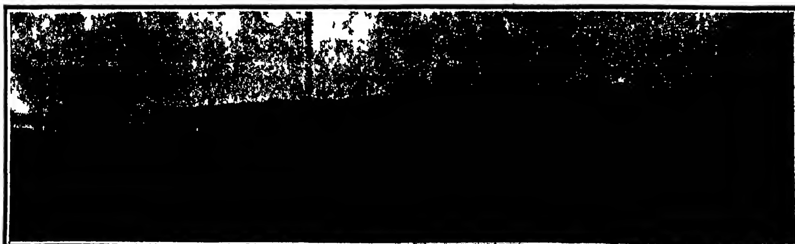
A little leaden tablet tarnished ugly and otherwise trivial in appearance was sent a few years ago from Athens to the Imperial Museum of Berlin. On one side of it is some writing which only recently was deciphered with precise correctness by Adolph Wilhelm, an Austrian *savant* who lives in Athens. The tablet is the original of a private letter that was written about the time of the orator Demosthenes.

The writer of the letter lived in a rural neighborhood and wished to send a commercial order to a town. The form of the address was: "To be taken to the pottery market and to be handed to Nausias, or Thrasykles or to the son" (perhaps the son of the writer was meant). The weekly market, to which the Attic countryman had gone to offer their produce and wares for sale may be imagined as in progress. There the boy who was bearer of the letter was to find the stand or booth of one of the three persons to whom it was addressed and deliver it to him. The text of the letter says: "Mnesiergos greets you cordially. He greets your family with the same esteem and wishes them good health, and he says also that his own health is good. Please be so kind as to send me a mantle either of sheepskin or of goatskin and let it be as cheap as possible for it does not need to be trimmed with fur. Send with it a pair of heavy soles also. As soon as I have an opportunity I will pay you."

So much for the letter, to the motive of which the reader can point with as much precision as the author. Apparently it was written in winter, poor Mnesiergos having been surprised out in the open country by one of those icy snowstorms which sometimes even at this day cover the temples of the Acropolis with a mantle of snow. Therefore he desired to receive as quickly as possible the heavy and warm garment of the poorer countrymen, a goatskin, which could be bought for four and a half drachmas, and the strong soles which were worn under the ordinary sandals on the rural plains and hillsides. A good pair of the latter could be bought for four drachmas as a well preserved bill of that date shows.

A noteworthy feature of this artless letter is the formula with which it begins, the very formula that may be found used in very numerous letters that were preserved by the Greek literature of later times. Even at the present day every letter written by a rural Greek begins with the same cordial inquiry about the health of the person to whom the letter is written and with brief information about the health of the writer.

Although it is possible to resolve into gas almost any kind of solid fuel in a gas producer it is well known that certain fuels—particularly those high in ash and of a caking character—give a good deal of trouble. One of the most serious of these troubles, states a contemporary, is that the fuel welds itself into a large mass which partially chokes the fire in some places and causes passages or holes to be burnt at others. Hence poking of the fire is necessary and the poorer the fuel the more the poking. In order to reduce this poking to a minimum some producer makers fit shaking or revolving grates. The latest design of this character is due to Mr. Chapman, an American, and it is a considerable extension of the principle. The lower portion of the producer is divided into two or three rings which are free of each other and rotate at different speeds, the joints between them being made by water seals. The object is to shake the fuel continuously so that caking or clogging and holes are equally impossible.



This little craft, 46 feet [illegible] inches long, carries its war head and engines in a suspended cigar-shaped hull which lies entirely below the waterline and therefore out of reach of the enemy's projectiles. The upper hull, being filled with cellulose, is designed to be unsinkable. In attacking the boat would be driven at the enemy at its full speed of 18 knots, and when it was within striking distance the crew [illegible] would jump overboard, locking the rudder and leaving the boat to explode its charge of 1,000 pounds of guncotton by bodily ramming the ship.

NEW TYPE OF [illegible] FOR THE NAVY

# TRACKLESS ELECTRIC TROLLEY-DRAWN SLEIGH IN NORWAY

BY FRANK C. PERKINS

The accompanying illustration shows a novel sleigh trailer in Drammen in service during the past winter in Norway as drawn by the trackless electric trolley.

The novel construction of the trackless trolley car of the A. S. Drammens Elektriske Bane is shown in the illustration as placed in operation by the Gesellschaft fuer Gleislose Bahnen Schiemann of Wurzen in Saxony, Germany. There are two overhead conductors provided along the Drammen River over the roadway for a distance of 3.5 kilometers (2.48 miles). The city of Drammen has about 25,000 inhabitants, who are served by this electric trackless trolley line. There are four motor cars in service, which have run 125,000 car kilometers (77,671 car miles) during the past year.

A direct current of 5,000 volts is used on the overhead trolley line, this current being supplied from a sub-station equipped with motor generators and step-down transformers. The current is generated at a hydro-electric power plant 40 kilometers (24.85 miles) away and transmitted to the sub-station at an alternating current of high voltage. The alternating current is transformed to a direct current by a converter of 90 kilowatts capacity. The cars weigh about 3,000 kilogrammes (6,614 pounds) each and are provided with rubber-tired wheels. An electric motor of from 15 to 22 horse-power capacity is utilized, which drives the trackless trolley car at a normal speed of about 20 kilometers (12.43 miles) per hour. The cars are lighted with five tantalum incandescent lamps of 32 candle-power each. It will be noted that the trolley pole is similar to those of American construction, but provided with two conductors and contacts of the sliding type for both trolley wires instead of the usual single trolley wheel used on electric railways.

A PASSENGER SLEIGH DRAWN BY A TRACKLESS ELECTRIC TROLLEY

Every winter the demand for fresh eggs becomes more insistent and more difficult to supply. Poultry breeders in different parts of the world have endeavored to supply the deficiency by artificial selection. By this process an Australian breed of fowls which averages 270 eggs per hen per year has already been produced. A series of very interesting experiments on the same subject has been carried on during the past ten years at Macdonald College, in Montreal, which is reputed to be the most perfectly equipped school of agriculture in America. Starting with breeds noted for their endurance of cold, especially Plymouth Rocks and White Wyandottes the experimenters began the process of selection by allowing the fowls to leave the poultry yard and scratch in the snow in the coldest weather. The progeny of the fowls which availed themselves of this privilege was subjected to similar treatment which was continued for several generations. The poultry houses were not heated, even when the temperature fell to zero Fahrenheit, although the fowls were slightly protected from the cold by screens placed around their perches. The poultry yards were covered with a layer of straw a foot thick, upon which wheat or millet, the only food given, was strewn at regular hours. The hens were kept busy from morning until night in hunting for their food in the straw. This active exercise prevented the accumulation of fat and stimulated the production of eggs, for every poultry farmer knows that fat hens are poor layers. Hence, as hens, like all other birds, naturally store up fat at the approach of winter, the problem became limited to preventing this accumulation of fat, and at the same time assuring to the hens an abundance of food. The problem appears to be in a fair way of solution for the hens of Macdonald College produce an average of 200 eggs per year, from one-fifth to one-fourth of which are laid during the rigors of the Canadian winter.

The removal of ashes by conveying them to a waste bank hydraulically is done in connection with the temporary plant built to supply power during the construction of the Rainbow Falls hydro-electric development of the Great Falls Water Power and Townsite Company on the Missouri River near Great Falls, Mont. The power house is on the side of a hill directly above the edge of the river bank. The bituminous coal used is dumped by gravity from cars on a trestle to a bin at the rear of the firing floor of the boiler room and runs down on this floor, from which it is fed by hand to the furnaces. As the ashes fall through the grate they are drawn out into a transverse concrete lined trench in the firing floor. This trench is sloped to one side of the building, where it connects with a flume extending on a grade of about 5 per cent to the edge of the river bank. When the grates are cleaned the ashes are pulled into the trench and a hose stream turned into the latter to start them. They are thus picked up by and carried out in the river through the flume. No difficulty is experienced from clogging in the trench or flume and the current in the river prevents an accumulation at the edge of the bank.

# THE EARLIEST STORY OF THE DELUGE

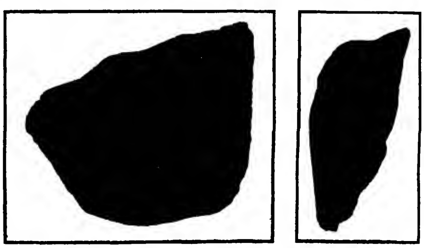
## PROF. HILPRECHT'S REMARKABLE DISCOVERY

One of the most remarkable discoveries which has ever been made in Assyriology, a discovery which redounds greatly to the credit of the University of Pennsylvania and to the credit of Prof. H. C. Hilprecht, is the finding of an account of the Babylonian Deluge which antedates any Deluge narrative extant. The significance of the discovery is enhanced by the fact that in the most important details it agrees remarkably with the Biblical version of the Deluge, much more so in fact than any other cuneiform version thus far unearthed.

The work of Prof. Hilprecht is of fundamental importance for the correct determination of the age of Israel's earliest traditions, for the Nippur tablet, upon which the story is written, was inscribed before Abraham had left his home in Ur of the Chaldees.

Upon Prof. Hilprecht's recommendation that his discoveries be made accessible to the scientific world as quickly as possible, a paper by him has recently been published by the University of Pennsylvania, which bears the title, "The Babylonian Expedition of the University of Pennsylvania. Series D: Researches and Treatises. Vol. V Fasciculus." From this paper the following abstract is made:

Toward the end of October, 1909, while unpacking and examining two boxes of cuneiform tablets from the fourth expedition of the University of Pennsylvania to Nippur, Prof. Hilprecht's attention was attracted by some fragments which presented certain peculiarities, and which, unlike the others in the boxes, were not written in Sumerian, the ancient sacred language of Babylonia, but in the Semitic dialect of the country. This fragment was so completely covered with crystals of niter and other sediments that, when taken out from its paper wrapper, at first only a few cuneiform signs could be recognized. Three characters in particular, standing together in the upper section of the fragment, were fortunately free from incrustations. The words were *a-bu-bi* "deluge." Prof. Hilprecht's attention was naturally aroused. For three continuous weeks he personally spent from one to two hours every day endeavoring to uncover one cuneiform character after another by removing the incrustations and other deposits of hardened dirt without damaging the writing below, until he had completely deciphered every sign. The fragment proved to be a somewhat incomplete but unmistakable account of the Deluge about 1500 years older than similar fragments obtained from the library of Ashurbanapal (668-626 B. C.) and was inscribed more than 600 years before the time generally assigned to Moses, and even before the Patriarch Abraham rescued Lot from the hands of Amraphel of Shinar and Chedorlaomer of Elam (Genesis 14). Furthermore in its preserved portion it showed a much greater resemblance to the Biblical Deluge story than any other fragment yet published.



FRONT AND EDGE VIEWS OF THE NIPPUR VERSION OF THE DELUGE. DATE, APPROXIMATELY, 2100 B. C.

The cuneiform text of the fragment contains a portion of the divine command to the Babylonian Noah, Ut-na-pishtim to construct a ship and to save life from the all destroying flood. Apart from the tradition of a great flood handed down by the Babylonian priest Berosus (living between 330 and 250 B. C.) but preserved only in extracts by other ancient writers there are fragments of three distinct Deluge versions in cuneiform writing.

The first of these is the version from the library of King Ashurbanapal (668-626 B. C.) which was restored from a number of fragments found in the ruins of Nineveh, and which is an Assyrian copy of a Babylonian original.

The second is a somewhat different version of the Babylonian Deluge story and is found on Fragment "D(aily) T(elegraph) 42," which likewise came from the royal library of Nineveh and was inscribed about the same time (c. 650 B. C.).

The third fragment is that acquired and published by Prof. Scheil of Paris, and now in the possession of Mr. J. Pierpont Morgan. It is dated "in the year when King Ammi-zaduga built Dur-Ammi-zaduga at the mouth of the Euphrates," i. e., the eleventh year of his government, in other words, according to Prof. Hilprecht's reduced chronology, about 1868 B. C.

An examination of the cuneiform text of the Nippur fragment and a comparison of this new version of

the Babylonian Deluge story with the parallel passages of the two Nineveh versions and the Biblical story have brought out the significant fact that, with all due allowance for a general resemblance between the three cuneiform versions, the Nippur version of the divine announcement of a great flood and the command to build the ark differs fundamentally from the two Nineveh versions and agrees most remarkably with the Biblical story This agreement affects that part of the Pentateuch (Gen 6 13-20 8 11) which Old Testament critics style P (= Priestly Code) and generally regard as having been "compiled in Babylonia about 500 B C" The importance of this new text to theological students cannot be overrated Written as it was about 2100 B C, this new version came into being at a time when the sanctuary of Enlil at Nippur was supreme among the Babylonian temples and was the center of literature When Hammurabi, the Amraphel of Genesis 14 conquered Rim-Sin of Larsa, the various petty Babylonian states constituting geographically the ancient kingdom of Shumer and Akkad were united politically by the conqueror Babylon on the Euphrates became the metropolis of the united empire After Ammi-ditana the third successor of Hammurabi Nippur disappears rapidly from history It reappears with the rise of the Cassite dynasty in Babylonia about 1400 B C, and its sanctuary again rises to hold a conspicuous place for several centuries The revival is but the last flicker of a fast dying flame

In Prof Hilprecht's opinion the Temple Library at Nippur was a most insignificant institution after 1000 B C, and it flourished most gloriously before 2000 B C The priests of the Cassite and Neo-Babylonian periods produced few, if any original literary compositions of value at Nippur more delighting in the statement at the end of their tablets that the text was "a faithful copy of an old Nippur original" The literary activity of the priests was transferred to other centers like Babylon and Sippar It is therefore evident that the Nippur fragments, antedating the two Nineveh versions by 1500 years, represent the oldest version of the Babylonian Deluge story in a Semitic translation, made doubtless from a much older Sumerian original which has not yet been discovered and that the later cuneiform versions are different editions of the same story with considerable changes, abbreviations, and additions The Deluge story of the so-called "Priestly Code" must form part of the oldest traditions of Israel as Old Testament scholars have pointed out

Even the Amarna period (about 1400 B C) with its unsettled conditions in Palestine, when the influence of Babylonia upon the shaping of the government and the religious conceptions of Palestine was almost nil cannot explain its presence in the Old Testament. The only period when the oldest version of the Deluge story could possibly have entered Canaan was the time when Abraham, whom Prof Hilprecht regards as an historical personage, left his home on the Euphrates and journeyed westward, in other words, the period of the first dynasties of Isin and Babylon of which Hammurabi or Amraphel is the central figure, the time when the Amorites knocked at the gates of Babylonia, invaded the country, and soon overthrew the old dominion

Although the interpretation of the Nippur tablet is by no means easy it can be stated with safety that in accordance with the exalted position held by Enlil in the old Babylonian pantheon as "father of the gods" it was in all probability Enlil himself who warned Ut-na-pishtim to take refuge in an ark Here then as in the Biblical version, the Lord of the Universe himself both causes the Deluge and saves Noah from destruction by warning him and ordering the construction of an ark

We present herewith in parallel columns the translation of the actual preserved portions of the ancient Nippur version and the corresponding passages of the Old Testament according to the Hebrew text. The similarity is at once striking so much so in fact that the blanks in the Nippur version can easily be supplied by the more complete account

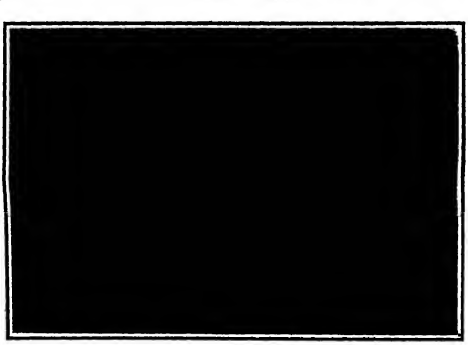
| Line | Nippur Version. | Biblical Version (Gen 6 13-20 7 11) |
|---|---|---|
| 2 | I will loosen." | 7 11) "all the fountains of the great deep were broken up, and the windows of heaven were opened." |
| 3 | "It shall sweep (or 'take') away all men together" | 6, 11 "behold, I will destroy them with the earth." |
| 4 | life 1?) before the deluge cometh forth" | 18 "but with thee I will establish my covenant" |
| 5 | (over) "as many as there are, I will bring overthrow, destruction annihilation | 17 and behold I do bring the deluge upon the earth to destroy all flesh, wherein is the breath of life, from under heaven, everything that is on earth shall perish |
| 6 | "build a great ship and" | 14 "make thee an ark. " |
| 7 | "total height shall be its structure" | 15 "and thus thou shalt make it and thirty cubits its height" |
| 8 | "it shall be a house-boat carrying what has been saved of life" | 16 A roof shalt thou make to the ark, in its (entire) length thou shalt cover it and the door of the ark shalt thou set in the side thereof (with) lower, second and third stories shalt thou make it" |
| 9 | "with a strong roof over it | |
| 10 | (the boat) "which thou shalt make" | 19 And from every living thing from all flesh two from everything shalt thou bring into the ark, to keep them alive with thee, they shall be male and female" |
| 11 | "instead of a number" | 20 (two) from the birds instead of a number thereof, (two) from the beasts instead of a number thereof (two) from everything creeping on the ground instead of a number thereof." |
| 12 | and family" | 18, b "and thou shalt come into the ark, thou and thy sons, and thy wife, and thy sons' wives with thee." |

### The Current Supplement.

The current Supplement, No 1787, contains a most remarkable number of interesting articles. Karlornst Knatz writes on the modern use of police dogs, and R W Raymond on quantitative and qualitative thinking. Prof R S Woodworth deals interestingly with the "typical" man a creature who does not exist, but yet who is very necessary in the endeavor to classify mankind A prominent place among the physical agents employed in modern methods of therapeutics has been occupied for the past decade by light and especially by electric light, which is used chiefly in the form of "light baths" and is furnished by arc and incandescent lamps separately or in combination Dr Theodor Schueler reviews these modern therapeutic agents in an article entitled "Electricity and Light in Modern Medicine" No name is more distinguished among modern astronomers than that of Prof G E. Hale, the foremost authority in the world on the sun He contributes a brilliant article on solar vortices and magnetic fields, in which he critically discusses recent solar investigations, and particularly his own wonderful discovery of the Zeeman effect in sun-spots In scientific research, as in less ambitious affairs, the possession of a good imagination is often of the utmost value There are few instances in which a closely reasoned sequence of ideas has been employed in the evolution of outstanding achievements, there are equally few in which the authors of these advances have not owed a large measure of their success to the happy inspiration of their imaginations, all of which is discussed in an article entitled "Scientific Guesswork." Although the port of Swansea is placed on the banks of the River Tawe, it may for all practical purposes be regarded entirely as an artificial port, the discharge of the river being trifling as compared with the volume of tidal water ebbing and flowing between the pierheads. The peculiar conditions of that port have necessitated the construction of a most wonderful dock, possessing a water area of 5 acres in addition to the area of the deep-water extension which, when it is completed, will add 40 acres to the total. This remarkable scheme is described by C Van Langendonck. C L de Muralt writes on modern development in heavy electric locomotives. Among the very subtle notions which often embarrass the teacher of mechanics, none more frequently leads to erroneous interpretations than the two aspects in which acceleration may be considered, but there is also none which when once mastered is more fertile of results in thorough instruction. For that reason teachers will no doubt read with interest Mr C E Guillaume's excellent article entitled "Paradoxes of Acceleration." One reason why the turbine has not completely supplanted the reciprocating engine in ship propulsion is to be found in the fact that it is not reversible, and in the second fact that screw propellers are most efficient at a rate of speed considerably lower than the rate of speed which is best for efficiency and economy of turbine operation. To overcome these drawbacks Dr H. Foettinger has invented a system for which he claims not only a high degree of efficiency, but reversible action without mechanical complications. The feature of this invention which is most thoroughly described in the current Supplement is a relatively light and simple hydraulic transmission device, the so-called turbo-transformer G H Bryan contributes some new ideas on the subject of aeroplane stability

### NEW AUTOMOBILE RECORDS AT ORMOND BEACH.

Once again the famous sands of Ormond Beach have been used for making new records with automobiles. During the three days' meet held last week Barney Oldfield once more beat the world's record for speed with his new 200-horse-power Benz racer, a picture of which is reproduced herewith. This machine broke four world's records last fall upon the Brooklands track in England, and so it is not to be wondered at that upon the smooth sands of Ormond it traveled two miles in the fastest time ever made by an automobile The distance was covered in 55 87/100 seconds, which is nearly three seconds better than the record of 58 4/5 made by Demogeot in 1906 with a Darracq car The rate of speed traveled by Oldfield is 128 89 miles an hour Oldfield also made new records for the kilometer and the mile; he covered the 3,280 feet of the first-mentioned distance in 17 4/100 seconds. The previous record was 17 76/100 His record for the mile, which was made a week previously, was 27 33/100 seconds, a speed of 131 72 miles an hour Walter Christie's front-drive racer covered this distance in 30 29/100 seconds, or at the rate of 118 46 miles an hour



THE 200-HORSE-POWER BENZ RACER IN WHICH OLDFIELD MADE 128 89 MILES AN HOUR. A NEW WORLD'S RECORD

In the stock car races, Oldfield made a new record of 40 35/100 seconds for one mile in a Knox machine. This make of car also won the 10-mile free-for-all in 8 41/100 minutes, a Chalmers 40-horse-power car took second place, the 10-mile handicap was also won by a Chalmers car, which beat the Pope-Hartford, the time being 12 minutes and 12 seconds. On the last day of the meet, in the one-mile speed trials, Oldfield covered the distance in 27 33/100 seconds. The 10-mile stock chassis race for cars having a piston displacement of 161 to 230 inches was won by Hart in a Buick in 12 minutes and 58 seconds, or at the rate of 46 27 miles per hour A Hudson machine came in second In the 10-mile handicap a Darracq car driven by Kirscher won in 7 21, Oldfield on a Knox was second and Bond on a Stearns third A second 10-mile handicap race was won by Altman on a Hudson in 12 46, Oldfield with a Knox was again second, and Kirscher third.

In the one-mile speed trials the Darracq covered the distance in 37.24, and Walter Christie made it in 33.15.

While the races this year were not very numerous, Oldfield created a great deal of enthusiasm by his record-breaking driving, and it is probable that next year still other attempts will be made to reduce the time for short distances. The machine Oldfield used is in every way similar to a regular stock car except that it has a much larger engine of 185 x 200 millimeters (7.3 x 7.9 inches) bore and stroke, capable of developing considerably more than its rated horse-power.

A large portion of the old French plant at Panama was found to be serviceable, and is doing good work on the canal. Since 1906 the useless junk has been sold as scrap, and up to January, 1910, over ten thousand tons have been shipped and sold.

### The Nature of the Interior of the Earth.

Especially during the past few years the structure and temperature of the interior of the earth have been an object of lively and insistent discussion, and not a lesser result of it is the plan to bore a hole to the kernel of the earth, by means of which may be investigated all the strata of the globe, which as they succeed one another toward its center indicate an increasing temperature in conformity to a law Flammarion particularly has quickened this question very recently, and with it has busied the fancy both of expert and of layman. As lending further vivid importance to the discussion, the gist of certain chapters of Dr W L Meyer's book, "Bewohnte Welten" (Inhabited Worlds), recently published, may be cited It affords a most interesting estimate of the temperature of the crust of the earth and of the interior volume of our native planet. This research discloses that the varying temperature of the atmosphere exercises an influence on the temperature of the crust of the earth only to quite inconsiderable depths. Already at a distance of fifteen to twenty meters below the surface a uniform temperature of 9 deg Celsius approximately has been ascertained, which prevails around the whole earth. With increasing depth the degree of heat is enhanced. This increase is called the geothermal degree of depth. In many holes that have been bored it varies with much frequency Generally 1 deg of increase of temperature of rock is indicated as often as 33.3 meters of greater depth are added. This result is due to the mode of observation that informs us of the characteristics of two kilometers, or the thirty-two-hundredth part, of the distance toward the center of the earth. Here at this depth a temperature of 50 deg was ascertained. If this manner of calculation be continued for greater degrees of depth the immediate result is that already at 60 kilometers, approximately, the constituents of the crust of the earth are in fiery solution, and at 300 kilometers must be in the form of gas. The latest investigations conducted by Meyer remind us of the research of Tamman and others and of the results of experiments made to measure the speed of the progress of waves of seismic disturbance. The collective result leads to the conclusion that the real firm crust of the earth cannot be specifically thicker than 100 kilometers. Among the phenomena sustaining this conclusion is the so-called magma which is occasionally expelled in a volcanic eruption, when nearer to the center of the earth it has the form of gas, but under such stupendous pressure that at the distance aforementioned the substance seems to have the appearance of wax. So it is assumed that the temperature of the center of the earth lies between 20,000 and 100,000 deg

At this juncture Dr. Meyer seeks to satisfy the curiosity of the inquirer with his statement of the equation of heat that occurs between the earth and the sun; the store of heat, great beyond human computation, that streams forth over the geothermal degrees of depth from the interior of the earth into endless space is so far counterbalanced by the heat imparted to the earth by the rays of the sun that no decrease of the mean temperature of the surface of the earth can be ascertained It must be noted therefore, that as on the temperature of the earth depend the most important processes of life, these are assured for an indefinite time at least.

### An Eruption of Etna.

On March 24th the Sicilian volcano Etna began to erupt. The lava united in a vast stream 24 feet high and 1,800 feet wide, and at the time of going to press was threatening the destruction of Belpasso and Borello.

The lava devastated large tracts of cultivated lands, such as vineyards and orchards, and has wrought havoc in the woods. The village of Nicolo, near Nicolosi, has been covered completely, and many huts and farmhouses have been destroyed.

### BUILDING THE HUGE CONCRETE LOCKS AT GATUN, PANAMA.

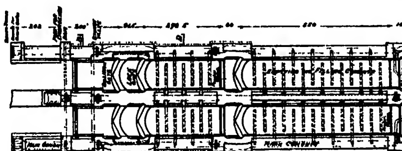
SPECIAL APPLIANCES BY WHICH THIS HUGE ARTIFICIAL MONOLITH, 400 FEET WIDE, 4,000 FEET LONG, AND 90 TO 100 FEET DEEP, IS CONSTRUCTED

The work at Panama, and particularly at the great flight of double locks at Gatun, has now reached a stage at which the camera is able to catch some adequate impression of the titanic proportions of the work and record it for the interest of the outside world We have all understood that the scale upon which work was being done at Panama was impressive, but it remains for the accompanying pictures to teach us just how stupendous is the mass of masonry which is slowly taking shape near the Atlantic end of the canal.

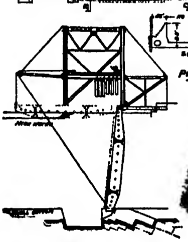
The locks at Gatun will pass vessels up or down between sea level and the level of the lake which will be formed by the great Gatun dam immediately adjoining the locks. The total height of 85 feet will be covered in three flights of approximately 28 feet each. In order to provide ample accommodation for future increase in traffic, and also as a contingency against total disablement of the locks, they are being built in duplicate, as shown in the plans herewith presented Each lock will be 110 feet wide, and will have a usable length of 1,000 feet To provide against the carrying away of gates and the consequent rush of water out of the lake the former will be built in duplicate, with a considerable space of water between them, so that if a ship, overrunning, should strike the first gate, the second will remain intact Also, at the entrance to the upper lock, there will be a huge swing bridge which, in the event of the gates being carried away, can be swung across the lock entrance, and a series of horizontal, vertically sliding steel gates lowered down from the bridge, thus effectually shutting off the flow of water Heavy fender chains will also protect the gates by receiving the first shock of a collision and thus, partially if not altogether, absorbing the momentum.

But the present story is concerned with the methods which have been adopted for building this huge monolithic, or unjointed, mass of artificial masonry, into the construction of which will enter about four million cubic yards of concrete In general, the locks may be described as consisting of a floor, 400 feet by 3,800 feet in area, and of 20 feet maximum thickness, of two side walls, 50 feet in thickness at their lowest part, and of a central dividing wall, 60 feet thick (See diagrams.) The clear height of these walls from the floor of the dock to the coping is 68 to 86 feet. The inner faces forming the sides of the lock are vertical. The outer faces are built on an incline and are stepped, the horizontal thickness increasing with the depth of water in order to resist the lateral pressures For emptying and filling the locks a series of transverse culverts, formed in the floor, lead to large longitudinal culverts in the base of the walls (Figs. 1 and 8), the latter ranging in diameter from a minimum of 18 to a maximum of 22 feet, the size varying according to the number of side culverts that are served. Now it can readily be understood that the cost of a work of this kind, involving the handling of 4,000,000 cubic yards of material, depends very largely upon the amount of labor involved For in works of this character the cost of labor is the principal item, and hence much thought has been given to the design of the appliances for handling the concrete and the huge "forms (temporary inclosing walls) within which the concrete is deposited At the Gatun locks the sand and stone are deposited from cars in a stock pile running parallel with the lock site On either bank above the huge excavation in which the locks are being built are a series of lofty steel towers (see front page and Figs. 2 and 7), between which are strung heavy, steel cables, by which the buckets containing the materials are transported The concrete is picked up by these cables run over the excavation and lowered at the desired point

The first part of the concrete work consisted in the laying of the huge slab of concrete, 392 feet wide and nearly 4,000 feet long, with a maximum thickness of 20 feet, which forms the floor of the locks. During the construction of this floor, care was taken to provide circular transverse conduits with vertical openings through the floor which led alternately to opposite side walls, there to connect with the main longitudinal, emptying and filling conduits. The next task was to erect the side walls, and it is this interesting work which is shown so clearly in the accompanying illustration



PLAN AND SECTIONS OF GATUN LOCKS



Cross-section of emergency dam in the closed position, with wicket girders down and sliding gates partly in the lowered position

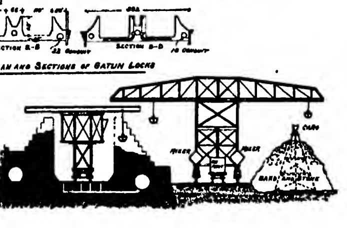


Diagram showing method of building the locks Sand and stone are lifted from the stock pile to the mixers, and from the mixers the concrete is carried to the lock site by the two cantilever cranes

How the 4,000,000 cubic yards of concrete are being mixed and built into place at the Canal locks.

BUILDING THE HUGE CONCRETE LOCKS AT GATUN, PANAMA

The walls are built in sections, each of which is about 40 feet wide, with a space of about 30 feet between them The wall is then completed by filling in the intervening vertical gaps

It is well understood that one of the most expensive elements in concrete construction is the building and manipulation of the forms in which the concrete sets In smaller structures these are composed of timber, but because of the huge amount that would be required and the big depreciation in the value of the timber after use this material was altogether out of the question The plan adopted is shown very clearly in our illustrations The forms are built entirely of steel (Figs 2, 4 and 5) Those for the inner vertical face of the walls consist of a series of massive steel towers of a triangular cross-section, to the vertical face of which is riveted a wall of steel plating, stiffened by horizontal channel irons. The towers are carried upon four 4-wheel trucks, two under the front and two under the rear face, which run upon two pairs of rails laid on the floor of the lock and parallel with its longitudinal axis The rear face of the walls, which is stepped, closed by a series of separate rectangular forms measuring about 6 feet on the vertical and 4 feet on the horizontal face The ends of each wall section are closed by means of steel plates supported against vertical movable framework Into the pocket as thus formed the concrete is dumped from the skips of the overhead cable, and tamped into place by the laborers, until the full 6 feet of height corresponding to the height of the rear stepping is completed The walls are thus carried up three at a time until they have reached their full height This work is very clearly shown in the front page engraving, where a skip is shown as having just delivered its load and the laborers are spreading and tamping the concrete

To assist in making a firm joint between the monolithic sections, vertical and horizontal key ways or pockets (Fig. 5) are formed in the abutting faces, which pockets are, of course, filled in with concrete as the intervening gaps between the walls are built up This system of keying, coupled with the natural adhesion of the concrete, will prevent any tendency to cracking or separation of the walls at these points under hydraulic or earth pressure or under the racking strains of an earthquake shock

A most interesting piece of steel form work is that

for forming the 18 to 22-foot conduits in the side walls. It consists of a flexible steel pipe (Fig. 1) heavily braced to resist deformation, which has a longitudinal hinge at the top and at the bottom is provided with heavy left and right screws by which the form is kept to its full dimension during the laying and setting of the concrete. To remove the forms, the screws are turned and the bottom edges of the form are drawn together, thus reducing the diameter and allowing the form to be drawn clear of the conduit.

A most interesting picture is Fig. 3, showing the work at the entrance to the locks from Gatun dam. To the right is seen the rear stepping of the easterly wall of the easterly lock. The circular timber work shows the position of the upper end of the first lock. Just beyond this are two sections of the steel forms for the main central conduit by which water will be led from the lake to the upper lock. Just beyond the wall which extends across the picture to the right-hand bank will be located the emergency dam above referred to, and beyond, that will extend the three piers which will form the lock entrance from the lake. The embankment which will be seen running out as an extension of the natural bank to the right of the picture is the rock fill forming the southerly toe of the great Gatun dam, which extends to the right across the valley to a junction with the distant hills. The lake of water seen to the right of the rock embankment is formed by the hydraulic dredges which are being used in making the Gatun dam. Half a mile to the north, also extending across the valley from the northerly end of the locks, is a similar rock fill, and huge dredges are now engaged in pumping silt and water from the Chagres, and from the various contiguous channels, into the big basin half a mile wide and over a mile long thus formed. The water drains off through the rock fill, leaving the fine silt in a firmly compacted, impermeable mass, which is so dense that it will be impossible for the waters of the lake ever to seep through.

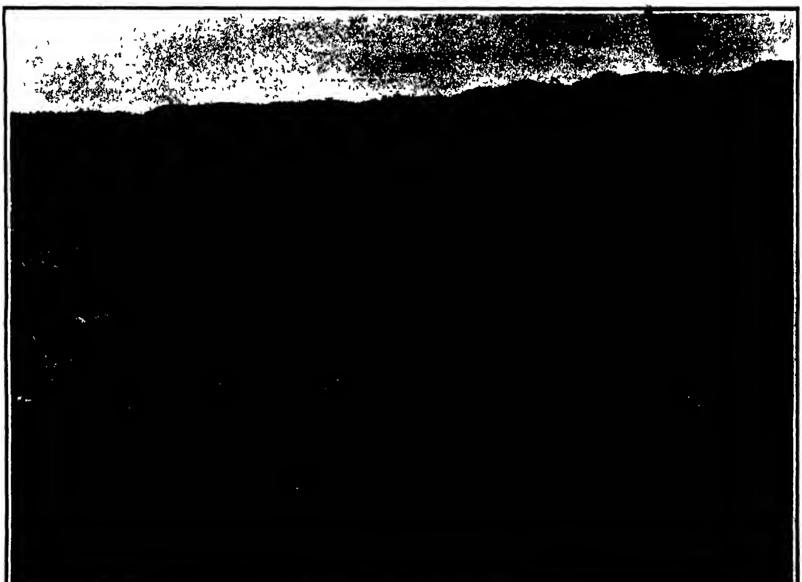
If the reader have sufficient imagination he can, by

The conduits are formed in the body of the side and center walls. The forms consist of collapsible steel cylinders, hinged at the top, split at the bottom and kept in place by big right and left screws. The latter are loosened when the concrete has set, allowing the two halves of the cylinder to swing inwardly and be withdrawn.

Fig. 1.—An 18-foot conduit for emptying and filling the locks.

Looking into the middle lock excavation from the east bank. To the left, section of side wall with forms yet in place. In center of excavation, the middle wall is being built in sections. To the right is a side wall section showing the movable form in place and a portion of the track upon which it is transported.

Fig. 2.—General view of middle lock.



In foreground is the timber form for upper end of upper lock. In center of stepped wall are the steel forms for conduit for filling the locks. Beyond the wall will be the emergency dam and the entrance piers, which will extend several feet into Lake Gatun. To the right is the rock fill which forms the southern toe of the Gatun dam. Back of it are the water and silt, which have been pumped up from the Chagres to form the main body of the dam.

Fig. 3.—General view of south end of Gatun locks.

BUILDING THE HUGE CONCRETE LOCKS AT GATUN, PANAMA.

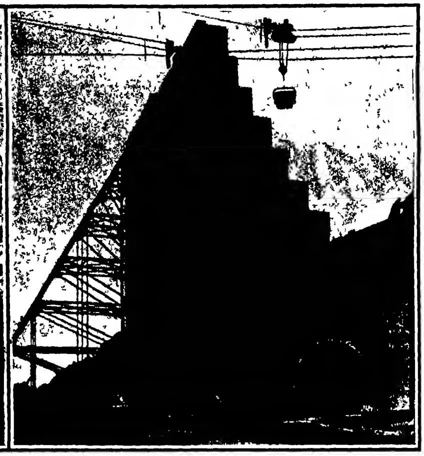
looking at this picture, fairly depict the scene as it will appear when the canal is completed, supposing, of course, the side wall were broken away to give him an unobstructed view. To the right the bank will be shut off by the walls of the lock structure, and to the left he will see the three concrete piers extending far out into a vast lake of water which will cover all the space now occupied by tracks, telegraph lines and embankments, and will extend in an unbroken surface until it reaches the hills in the far distance.

### Efficiency of Steam Turbine Nozzles.

Some experiments upon steam turbine nozzles, expanding steam from ordinary boiler pressures to condenser pressures, are described in a paper presented to the American Society of Mechanical Engineers by Prof. Sibley and T. R. Kemble. The main results are worth noting, and confirm the claims made for the efficiency of nozzles by turbine makers. Efficiences of from 90 to 95 per cent were regularly obtained. The actual discharge from the nozzles, stated as a percentage of the theoretical discharge, was of the same order as the efficiencies. Most interesting, however, was the apparent lack of influence exerted by the form of the nozzle, even when this might have been expected to be considerable, as, for instance, when the section changed from circular at the neck to square at the discharge, or when a conical needle protruded into the nozzle from the inlet end. Smoothness of surface was, however, an important factor.

These movable forms, consisting of vertical plate steel walls carried on trussed steel towers, are each mounted upon four four wheel trucks, and run upon two lines of double track, extending the full length of locks.

**Fig. 4.—Steel forms in place for building center wall.**



This is a completed section of the middle lock side wall. It is 80 feet wide by 81 feet high. In the base is one of the main filling and emptying conduits. The vertical recesses are to assist in keying the section together.

**Fig. 5.—A completed section of side wall.**

This wall, carried down everywhere to solid rock, will serve to prevent seepage of water through the earthen dam.

**Fig. 6.—Portion of concrete core wall, Miraflores dam.**

The gaps will be filled with concrete, keyed and cemented firmly in place, thus providing a continuous monolithic wall. The steel angle plate forms are already set up across the further gap.

**Fig. 7.—Sections of easterly side wall, upper lock.**

**BUILDING THE HUGE CONCRETE LOCKS AT GATUN, PANAMA.**

# THE HEAVENS IN APRIL

BY HENRY NORRIS RUSSELL, PH.D.

THE great comet which was so conspicuous in January is again observable in the morning sky, just before daylight but only with telescopic aid Its orbit is now well determined and it appears that it was nearest the sun, at a distance of 10,000,000 miles, about the time of its greatest brightness, and that its rapid fading was due to its steady recession from both earth and sun Its orbit is probably very nearly parabolic That it could not be of short period was clear at the time of discovery for so bright an object could not have escaped being seen often before, if it had come around at moderate intervals like Halley's comet

The latter is invisible behind the sun during the early part of April, but is well placed for morning observation toward the end of the month At this time it appears almost stationary in the heavens south of the eastern edge of the great square of Pegasus and is high enough to be observed before 4 A M Its distance from the earth decreases from 158,000,000 miles on the 1st to 77,000,000 on the 30th, and its apparent size and brightness will steadily increase By the end of the month it will doubtless be conspicuous to the naked eye

While waiting for this, we will find abundant occupation among the stars. Before we trace out the constellations into which the imagination has grouped them, let us study a *real* family of stars, whose relationship has but recently been discovered

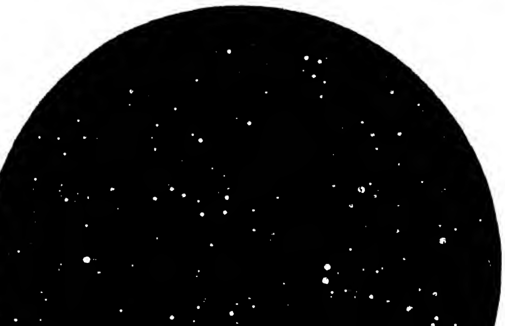
It has already been told in these columns how Prof Boss has identified about forty members of a group of stars in Taurus which are keeping together in their movement through space like a flock of wild geese in the air

It has also been known for some time that five of the bright stars of the Great Bear form a similar group, and recently, through the studies of two German astronomers, Ludendorff of Potsdam and Hertzsprung of Göttingen, it has been found that several other conspicuous stars, in different parts of the sky, also belong to it. All these stars are really moving in the same direction, and at the same rate, and hence they all appear to be moving away from the same point in the heavens, though in quite different directions, for some pass our system on one side and some on another They ought on this hypothesis still to be approaching us, and the spectroscope shows that this is actually the case the observed velocities of approach agreeing closely with those predicted by theory

The stars of this system are shown on our map First comes the group in Ursa Major—the stars $\beta$, $\gamma$, $\delta$, $\epsilon$, and $\zeta$, all in the Great Dipper—with Alcor the small companion of Mizar ($\zeta$), and also two other stars not shown on the map, one of them about a degree from $\epsilon$, a little above the line joining it to $\zeta$ and the other the northernmost of two fifth-magnitude stars not quite half way from $\beta$ toward $\nu$, which latter star is shown on the map north of $\theta$

All these eight stars are relatively about as close together as they look to us, and are at about the same distance from our solar system—65 to 75 light-years. This can be calculated with accuracy when once we know how fast they are really moving and how fast they seem to move The point from which, owing to perspective, the motions of all these stars appear to be directed is on the borders of Ursa Major, and is pointed out by a line from $\theta$ through $\kappa$ Ursae Majoris, carried as far again The other stars of the group are identified by the fact that their apparent motions are also directed away from this point, though they are widely scattered over the sky Two of them are nearly in line with the stars of the Dipper, though far removed on each side—$\beta$ Aurigae and $\alpha$ Coronae. The former is the remotest of the group, about 150 light years away, while the latter is about as far off as those previously described

Farther southward, in quite a different direction, is the star $\delta$ Leonis, whose calculated distance of 39 light-years puts it much nearer than these others, and suggests that direct observations of its parallax would be desirable Finally, and most remarkable of all the splendid Sirius is undoubtedly a member of the same group It owes its brightness to its relative nearness to us—only 8½ light-years according to the demands of theory which in this case is confirmed in a most satisfactory way by direct observation



At 11 o'clock Mar 8.
At 10½ o'clock Mar 16
At 10 o'clock Mar 23.

At 9½ o'clock March 30.

At 9 o'clock Apr 7
At 8½ o'clock Apr 14.
At 8 o'clock Apr. 22.

**NIGHT SKY: MARCH AND APRIL**

When the actual brightness of the other stars of the system is computed it is seen that Sirius is actually one of the fainter members of the system Its total light is about thirty times that of the sun while that of the principal stars of the Dipper and of $\alpha$ Coronae averages fully twice as much, and that of $\beta$ Aurigae is about 100 times as great Delta Leonis, on the other hand, is only about ten times as bright as the sun, and the fainter stars near the Dipper, belonging to the system, while still exceeding the sun in luminosity, are only two or three times as bright.

This system therefore consists of unusually bright stars It is remarkable also for the great extent in space Between the outer stars of the group there must be hundreds of stars, of which our sun is one, which have no connection with it. It is as if a dozen men were all walking through a confused crowd, all in the same direction and at the same speed. Though many of the crowd intervene, the mere fact of their progress toward the same point serves to distinguish them, and is a mark of their common origin.

It may be added in conclusion that a very large proportion of these stars, at least six out of the ten shown on the map, are either visually or spectroscopically double. Turning now to the constellations, we may fix our eyes first on the North [illegible] Little Bear, to which this belongs, while [illegible] the most conspicuous groups, is easily [illegible] a tolerably good "Dipper," though less [illegible] (if the phrase may be pardoned) than its larger [illegible]. The figure of the Bear, as shown in our [illegible], can hardly be made out except that th[illegible] ending in Polaris makes quite an [illegible]. Polaris itself, apart from its position, [illegible] as a double star, observable with [illegible], while the spectroscope shows that [illegible] of the two is attended by two invisible [illegible] with a period of less than three da[illegible] more remote, with one of several [illegible]

Around the Bear coils the [illegible], almost overhead, the Great Bear [illegible]. South of this we find the Lion, [illegible] the southern sky, the ungainly len[illegible] pent, Hydra. Above this come the [illegible] of the Crow and the Cup, and [illegible] all whose [illegible] surpassed [illegible] their companion. In the east we see the [illegible] Arcturus, and lower down the semicircle of the Crown, and Hercules [illegible] rising Passing around to the north, we find Cepheus and Cassiopeia, below the Pole, and then Perseus and Auriga in the northwest Taurus is [illegible] in the west, and Gemini above him, with the [illegible] Mars between the two. Orion and Canis Major are the southwestern sky, with Canis Minor above

THE PLANETS

Mercury is [illegible] a morning [illegible] the 5th, and [illegible] star after that date, but he will not be observable until the latter part of the month, when he sets an hour and a half after the sun and should be easily seen shortly after [illegible]. At this time he is in Taurus, and on the [illegible] he passes close to the Pleiades, which he much surpasses in brightness.

Venus is a morning star, rising about 4 A M on the 1st and 3 15 A. M. on the 30th She is extremely brilliant, and cannot possibly be mistaken

Mars is evening star in Gemini, slowly moving eastward among the stars and still losing in brightness as he recedes from us. He is very far north all through the month, and consequently remains in sight until after [illegible] P M

Jupiter is just past opposition, and dominates the evening sky Telescopically, the transits and eclipses of his satellites are among the most fascinating spectacles in the heavens, especially when the round black shadows of the satellites can be seen on the planet's disk, as happens on the 3d, 9th, 10th, 18th, and 25th during the evening hours in our part of the world.

Saturn is in conjunction with the sun on the 16th, and is unobservable throughout the month.

Uranus is in quadrature west of the sun on the 15th, and is observable in the morning Neptune, which is in a similar position on the opposite side of the sun on the 7th, can be seen, with a suitable telescope, in the evening.

The moon is in her last quarter at 3 P M on the 2d, new at 4 P M on the 9th, in her first quarter at 9 A. M. on the 16th, and full at 5 A. M. on the 24th. She is nearest us on the 10th, and farthest away on the 24th She is in conjunction with Uranus on the 3d, Venus on the 6th, Mercury and Saturn on the 9th—the three bodies being apparently close together, but also so near the sun that they cannot be seen—with Mars on the 13th, Neptune on the 15th, and Jupiter pretty closely on the night of the 21st.

Princeton University Observatory.

# NOVEL CHANGEABLE PHOTOGRAPHS

BY F. HONORE

Prof. Lippmann recently described before the Academy of Sciences at Paris some novel changeable photographs made according to a method devised by M. Estanave, secretary of the Faculty of Sciences of Marseilles.

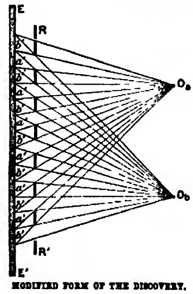
M. Estanave produced a dia-positive on glass of a sleeping woman. By inclining the picture a few millimeters and rocking it slightly, the eyes apparently open like the eyes of a porcelain doll, with the exception, however, that the entire face livens up in a most extraordinary manner. Incline the picture again and the eyes slowly close again. The photographs when reproduced for publication in a paper such as the SCIENTIFIC AMERICAN unfortunately cannot be used to obtain the effect because of the necessity of employing a special half tone screen.

In order to explain how M. Estanave obtains his picture, let us consider two different photographs—the one $D$ representing a sleeping woman, the other $E$ the same woman awake. Each photographic positive is ruled horizontally from top to bottom, so that both photographs appear finely banded. If we remove from the positive $D$ even alternate pairs of bands, and from the positive $E$ odd alternate pairs of bands, and if we place upon the positive $D$ the bands taken from $E$ and upon $E$ the bands taken from $D$, we will obtain two new pictures which we may designate $D^1$ and $E^1$. These new pictures $D^1$ and $E^1$ are composites of $D$ and $E$. If the bands are narrow enough, 30 per centimeter for example, their

THE SLEEPING WOMAN

discontinuity will not be noticed. The composite pictures will apparently be complete and comparable with the half-tone pictures to be found in the SCIENTIFIC AMERICAN or in any other modern illustrated periodical.

Let us now combine the two composites $D^1$ and $E^1$; in other words, let us transpose strips of $D^1$ and strips of $E^1$ without disturbing their order. We obtain still another positive $D^2$, formed by the combination of the two preceding positives. When looked



MODIFIED FORM OF THE DISCOVERY.

at directly this new positive $D^2$ is rather confusing, but when looked at through a glass plate ruled alternately with horizontal opaque and transparent bands of a width equal to those constituting the positive itself quite a different effect is obtained. If we hold this glass screen in such a manner that the opaque bands cover the bands of the positive $E^1$ we will see only the bands of the positive $D$, and we will obtain the portrait of a sleeping woman. On the other hand, if the screen be slightly shifted so that the bands of the positive $E^1$ are covered we will have a portrait of a woman wide awake. Since the different effects are obtained simply by shifting the screen, the single photographic view seen through it can be caused to change its appearance very rapidly simply by changing the speed of the screen movements.

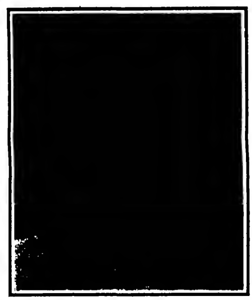
In actual practice the ruling of the positives and the transposition of the bands, as well as the use of a suitable screen, is attended with considerable difficulty. For that reason, M. Estanave has devised a simpler method which is illustrated in the accompanying diagram.

Let $a$ and $b$ be two different objects the luminous rays from which fall upon a sensitive plate or a ground glass $EE^1$. In the path of these rays at a suitable distance, the horizontal ruled screen $RR^1$ is placed. In the diagram the spaces separating the lines of the screen are considerably exaggerated and the screen itself is shown in vertical section. Such is the position of the screen that the sensitive plate will receive a series of images of $a^1$ alternating with images of $b^1$.

In making the positive photograph according to this method, the subject is first placed at $Oa$ and then at $Ob$. At $Oa$ the subject must appear asleep, and at $Ob$ wide awake. A composite picture will be obtained on the sensitive plate. If this picture be examined through a screen similar to that by means of which the picture was made, and the visual angle be varied either by shifting the eye or shifting the screen, the portrait will apparently open and close its eyes.

Theoretically several different pictures can thus be superimposed. In actual practice M. Estanave has combined three which are clearly visible. However there is a limit to the number of pictures that can thus be combined for the positives become more and more incomplete as the filiform bands composing them are more and more elongated. In the case of two aspects, the elements of an image are adjacent, the one to the other; with three aspects, the consecutive elements of an image are separated by two elements belonging respectively to each of the two other images, and so on.

In order to simplify the adjustment of the screen relatively to the composite image, and in fact to avoid adjustment entirely M. Estanave employs an improved auto-stereoscopic plate which he has invented. This plate is ruled with a screen on the side which is not emulsified, the rulings being such that alternate opaque and transparent bands are produced. The new invention of M. Estanave's is so conceived that the plate serves a double purpose. The plate is mounted with the ruled surface in front, or it can be so placed that the ruled surface is either horizontal or vertical. When the ruled surface is placed horizontally changeable photographs are obtained. With the ruling vertically placed images can



THE WAKING WOMAN

be obtained directly visible to the eye with a stereoscopic effect. With two stereoscopic lenses mounted so as to obtain filiform images formed by the superposition of the two images of the object taken under the same aspect, the vertical lines of the screen select for each eye the particular image of the stereoscopic couple which are intended for it.

### Mother-of-Pearl Imitations.

At a very early period repeated efforts were made to replace mother-of-pearl, so expensive at times, by some substance possessing the same valuable properties, but the results arrived at always fell far short of the expectations which were entertained, and these attempts were, therefore, gradually entirely abandoned. Recently attention has again been directed to the same problem, it being believed that the progress made in chemistry and applied science afforded grounds for hoping for more favorable results. And, in fact, some of the imitations of mother-of-pearl now made seem to show that these expectations will not be disappointed. It is true that hitherto but few detailed directions for making artificial mother-of-pearl have appeared in technical literature, for the simple reason that the methods which have led to successful results have for the most part been kept carefully secret, but a careful study of international patent literature shows that there are now various processes for making these imitations, some of them resting on a solid scientific basis. It is at once evident that imitations such as sheet gelatine steeped in fish-scale essence, or Cologne glue saturated with aluminium silver will never gain a footing as genuine substitutes when, for instance, not even the well-known celluloid mother-of-pearl can gain recognition as an equivalent. The purpose to which artificial mother-of-pearl is applied determines the degree of its efficiency as a substitute, and this degree of efficiency in its turn depends mainly on its external resemblance to the natural product. For combs, hat pin heads, etc. celluloid mother-of-pearl may be used without hesitation as an imitation, for ornaments, on the other hand, such as fastening pins, buckles, etc., the preference will naturally be given to substances whose external resemblance to the genuine material is complete or nearly so. Special interest, therefore, attaches to a new method of preparing artificial mother-of-pearl, which we proceed to describe in detail.

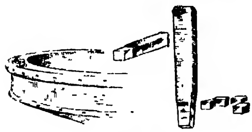
The ascertained fact that collodion, mixed with carbon bisulphide and a few parts of pearl-silver fluid, yielded a substance more or less resembling mother-of-pearl, led to a method of working directly with cellulose solutions, and in this way the celluloid mother-of-pearl already mentioned was obtained, a material which has been used for a variety of purposes in the industrial arts. As, however, the inflammability of celluloid considerably restricted the employment of this new material, efforts were made to replace celluloid by another substance. This substance was cellite. The process of preparing artificial mother-of-pearl from this base is as follows: 100 parts of cellite dissolved in 80 to 90 parts of glacial acetic acid or chloroform are mixed with 20 parts of calcined magnesia and 4 to 8 parts of pearl essence, with continual stirring. In this way a more or less viscid mass is obtained which is allowed to dry in the air. If a few drops of carbon bisulphide are added to the liquid solution a beautiful iridescent luster is imparted. As cellite dissolves comparatively slowly, it is advisable to prepare the solution a day or two beforehand. In case of need, the process of dissolving may be somewhat accelerated by slow heating in a water-bath. When dry the artificial mother-of-pearl presents the appearance of polished mother-of-pearl plates but in addition it is distinguished by great ductility and elasticity. The treatment of this artificial product is, therefore, much easier than that of genuine mother-of-pearl. It has also been attempted to substitute mother-of-pearl dust for magnesia and very satisfactory results have been obtained in this way. It is also possible by means of this process to produce artificial pearls exactly like real ones. For this purpose the artificial product is prepared in rather thick plates from which sticks are cut and pearls of any desired size and form turned on the lathe. These pearls are superior in point of resemblance to the natural product to the fish or wax pearls hitherto made from glass and are not so brittle as the latter.—Deutsche Goldschmiede Zeitung.

# NOTES ON OVERHAULING A BOAT

BY ALBERT F. BISHOP

Square Bunging for Boats.—I think square bungs are a big improvement over round bungs. They do not weaken the planking or chafing streaks and may more quickly be inserted.

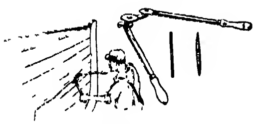
The chafing streak on a round stern that has been bunged with round bunging invariably breaks sooner or later where the round bungs have been inserted. Where the square bung is used the nail is driven and



SQUARE BUNGING

set. The square punch which is a trifle larger than the nail head, is then driven in making the aperture for the square bung. This punch should be hardened and ground on an emery wheel making the corner just as keen and sharp as possible. Oblong rectangular bungs are preferable where the boat nail is used in planking etc. The bungs are quite easily made 5/16 of an inch square with a small buzz saw, tilting the saw table slightly to produce the taper on two sides of the bung.

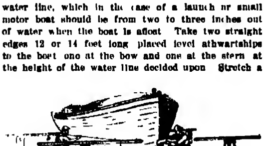
Wheel Calker.—The wheel calker illustrated herewith will easily force cotton into solid wood where there is no seam or joint. The shape gives one considerable leverage. The cotton is first placed along the seam by attaching it with the point of a knife at short distances, just enough to keep it in line with



WHEEL CALKER.

the joint. It is now ready for the knife shaped wheel, which calks it very rapidly. Take a strip of iron ⅝ by ⅛ inch thick, 2½ feet long and bend it to a flaring U shape. The bottom of the U should be 4 inches across and to it the wheels are riveted. The iron strip should be drawn down a little on the ends to receive the handles. The wheels are 1¾ inches in diameter. One of the wheels has a square edge 1/16 of an inch thick. The other wheel is 3/16 of an inch thick with the edge sharpened like a knife. There is a simple gauge placed on the framework near the square edged wheel which allows one to force the cotton to the desired depth to receive the putty.

Marking the Water Line on a Boat.—Level the boat athwartships and decide where you would like your water line, which in the case of a launch or small motor boat should be from two to three inches out of water when the boat is afloat. Take two straight edges 12 or 14 feet long placed level athwartships to the boat one at the bow and one at the stern at the height of the water line decided upon. Stretch a



MARKING THE WATER LINE ON A BOAT.

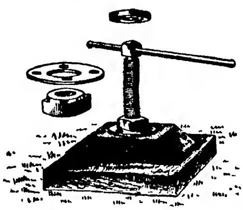
cord across the straight edges with the weight at each end to keep it taut and let it just touch the bilge of the boat so that you may dot your water line along the hull. The proper way to make a true line is with a thin batting 3 or four inches wide and 10 or 12 feet long with the upper edge pressed against the boat to correspond with the dots. Be particular to keep the batting exactly plumb edgeways and you can correctly scratch in your water line.

Simple Method of Weighing a Boat.—Take a lever six or eight feet long, place a fulcrum on the ground near the bow. Let the fulcrum (at 2 in the drawing) be just six inches from the end (1) of the lever that is under the bow of boat. A person that would weigh, say a hundred and fifty pounds, should work along on the lever, say to 3 or until the weight of his body would just lift the bow of the boat clear of the block ing. With a piece of chalk make a mark on the lever at this point. Divide the distance from the fulcrum to the chalk mark into 6-inch spaces and add 150 pounds for each space. For instance, eight space

WEIGHING A BOAT WITH A LEVER.

would mean 1,200 pounds, which would be a little less than half the weight of the boat, as the bow end is generally the lighter. Now raise the stern with the lever in the same manner. The boat being heavier at this end will call for more spaces. When this weight has been determined add the two weights and the result will not be far out for the entire boat. The blockings the boat rests on while the boat is lifted should be at the extreme end.

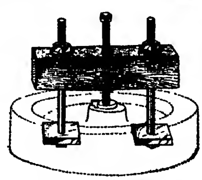
A Home-made Lifting Jack.—The jack here illustrated is made with a screw an inch in diameter and eight or more in length and a good heavy nut, the corners of which have been notched down with a file to receive a heavy washer. The part of the nut which comes through the washer should come through far



A HOME-MADE LIFTING JACK.

enough to allow for good heavy riveting on the washer. This makes the base for the nut to rest on and it is then placed on a wooden block, which is well secured with four wood screws. The base of the jack is a heavy block placed with the grain running at right angles to the upper block which holds the nut. The cap and lever require no description. The broad base prevents the jack from settling in the earth and from capsizing as well, which is a good feature around boat work.

A Home-made Wheel Puller.—A simple wheel puller can be made by taking a piece of maple about 3½ inches square and about sixteen in length and fitting it with the bolts about as shown in the accompanying sketch. The nut for the center screw has the washer

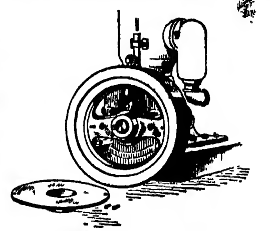


HOME-MADE WHEEL PULLER.

attached to it in the same way as in the lifting jack and it is similarly attached to the maple. The wheel bolts carry two broad nuts to catch on the rear face of the web or spokes of the wheel. The wheel is shown in dotted lines. This device is often resorted to in removing wheels from gasoline engines. This implement and the lifting jack have been in use four or five years. They have stood lots of wear and apparently are as strong as ever. A greater leverage on the wheel puller is obtained on the outside [illegible] with any suitable wrench.

Convenient Flywheel for Gasolene Engines.—[illegible] all the flywheels for small marine gasolene engines are filled up with spokes or webs with few holes in them, which makes it very awkward to get at the eccentric strap and pump to tighten the nuts and stuffing box. Nearly every time this is done the man in charge of the engine uses a cold chisel or screwdriver [illegible] a hammer. I have designed a wheel and used it [illegible] engine for four years. It has only two [illegible] a hand rim, doing away with the cranking [illegible], which is a dangerous feature. The plate [illegible] floor covers the key as well as the spokes, [illegible] tached with two machine screws.

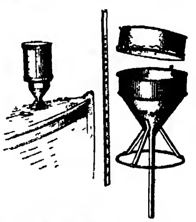
This makes a very tidy looking wheel [illegible] lutely safe because there is no danger of [illegible]



A CONVENIENT FLYWHEEL.

caught in the spokes. It is a great convenience in cleaning behind the wheel or repainting, as it does not take a minute to remove the cover [illegible] desired. A wrench is the proper thing to [illegible] nut instead of a cold chisel. It can be done [illegible] this style of wheel is used.

Tunnel for Gasoline.—The tunnel here shown is a practical one. You can capsize a five gallon [illegible] of gasoline and allow it to rest in the tunnel until it is empty, as illustrated in Fig 1. A breeze of wind will not blow it one side slopping it over, which always happens when trying to pour out of the can into the ordinary tunnel. The practical tunnel has a long piece of ⅝ inch tubing which goes well down into the tank



IMPROVED GASOLINE TUNNEL.

and should always be smaller than the receiving hole in the gasoline tank. The supports for the tunnel are made out of galvanized iron 1 inch wide and 1/16 thick, bending the upper end to conform to the angle of the cone while the lower end is bent around a 3/16-inch galvanized wire hoop about ten inches in diameter. A trifle larger than the upper part of the tunnel is good proportion.

This part of the tunnel is a standard article which can readily be procured. The parts that are attached are well soldered. It is not necessary to rivet them. Place a wire gauge about fifty or sixty mesh to the inch inside of the tunnel. If a chamois filter is desired make a band of metal that will easily slip inside of upper part of the tunnel. The lower end of this is covered with chamois, which is held in place with small twine. Tack a strip of vulcanized fiber to the measuring stick.

The graduations of gallons should be marked with lamp black mixed with shellac. The vulcanized fiber turns a sharp and [illegible] shade when dipped in gasoline, which is readily seen.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

ATTACHMENT FOR GARMENT-SUPPORTERS.—J. S. MARTIN, New Holland, Pa. The purpose of this invention is to provide an attachment which can be used in place of buttons, and which will cause the supporters to have a central draft on the garment instead of holding the garment up from one of its sides, whereby the garment will be so supported that it will be more comfortable to the wearer and will hang in better shape.

### Electrical Devices.

TELEPHONE-TRANSMITTER.—W WHITNEY, Schenectady, N Y This invention is adapted for use in connection with heavy currents. It contemplates such a distribution of the carbon granules employed in the transmitter, that the current used may be employed as a slowly pulsating current, a rapidly pulsating or an alternating current, by merely changing the electric connections.

### Of Interest to Farmers.

COTTON BALING PRESS.—E. A. WITHERS, Atlanta, Ga. An object here is to provide a cotton tamper driven by a slow acting power screw, in which the movement of the head is increased, thereby decreasing the time taken in pressing the successive changes, with means for changing the attachment of the head so that the movement of the power screw may be communicated directly to the latter, thereby increasing the power for baling purposes.

EGG CANDLING AND PACKING MACHINE.—H PIPPAS, Yebling Neb The inventor provides a machine that holds for a short time the eggs being treated in position to be subjected to a light test for decomposition, and provides a machine which will automatically pack eggs in suitable receptacles. The machine is simple in construction and requires the attention of but one operator

### Of General Interest.

CURRENT WATER WHEEL.—L. LAMERT, Brownstown, Ill This wheel is of the kind adapted to be set in the side of a bank or at the end of a jetty so that the working half of the wheel may be exposed to the current. An object of the invention is to form a simple and efficient water wheel, which will utilize the energy in a flowing stream without the necessity of building a dam or the like.

MUSICAL GARDEN ORNAMENT.—A S. JAKOBSON, New York, N Y This ornament is for use in houses and gardens. It is beautiful and attractive to the eye, and produces by the action of gentle breezes thereon, a ringing sound of such ethereal sweetness and such delicacy and variety of tones which will appear to be at a great distance and yet indefinitely near, so that they will produce an almost magical soothing effect on the hearers.

PROPELLER-GUARD.—J L. HAWTHORNE, Paterson, N J To overcome the danger of submerged rocks, the inventor has designed a propeller guard which in general consists of a frame extending beneath the propeller shaft and propeller, both the shaft and guard being supported to swing upwardly when the guard strikes an obstruction, thus allowing the propeller to ride safely over

SCAFFOLD H O COFFIN, Terre Haute, Ind In the present patent the invention has reference to scaffolds, and it has for its object the provision of a scaffold which can be quickly erected or dismantled and one which when in position will afford a strong and ready support. All the parts are capable of being quickly packed for transportation.

COMBINED CANE AND CAMP-STOOL.—M KILIAN, Elkton, Colo. This folding device can be easily carried about and will serve not only for a seat when unfolded, but may serve as a walking stick or cane when folded. The main folding parts are so arranged that when folded they will fit together so as to make a compact structure without sacrificing in any way the strength of the supporting members.

ANCHORING BASE FOR POSTS.—P T BAILEY, Newport, R. I. The object of this inventor is to provide a base in which there are two sets of anchoring spikes which may be driven into the ground after the base is set in position. The base has means for adjustably supporting a fence post, whereby the post may readily be alined.

FLASH-LIGHT.—H. A. WHITFIELD, New York, N Y In this case the object is to produce a flash-light having improved means for holding and exploding a cartridge or flash powder and further, to provide a construction which will enable the device to be used also for supporting and firing flash papers or flash sheets.

DERRICK DUMPING DEVICE.—C. H. PETERS, H. HART, and S. C. [illegible], Brown Station, N. Y. The device is arranged to permit of tilting the bucket at any time or in whatever position the boom may be in at the time For this, use is made of a dump drum and a dump line adapted to be wound up or unwound on the drum, the line passing from the drum through a sheave block, swiveled on the lower end of the mast, to then pass over [illegible] means on the upper end of the mast [illegible] the outer end of the boom, to [illegible] bucket to tilt the latter.

### Hardware and Tools.

TOOL-HOLDER.—E. RAWSON, Lewiston, Idaho. Means are provided by which the tool may be quickly applied and detached from the holder, consisting of a locking member journaled in the spindle, a clutch, a wrench journaled in the clutch, movable into and out of engagement with the member, and means for moving the clutch to engage and lock the spindle against rotation during the operation of the wrench

SEAL-HOLDING MECHANISM FOR LOCKS.—C H JOHNSON, Petaluma, Cal. This hasp lock has novel details that enable the retention of a paper seal within the lock over the keyhole therein which, if perforated, or removed after the lid has been closed and secured by the lock, will expose the fraudulent opening of the lock, and receptacle upon which it is mounted

WRENCH.—H HAND and T HAND, Seattle Wash This improvement provides a wrench which can be used either as a pipe wrench or for turning nuts. The wrench is self adjusting from about one-half inch to about a two-inch tap or nut, is so constructed that it has no weak parts to spring or to get out of order, and can be made in different sizes to suit a particular purpose.

INKSTAND.—J J HOEY, New York, N Y The aim of this inventor is to produce an ink stand enabling the ink to be readily accessible to the pen whatever may be the quantity of the ink in the stand, and to provide an arrangement whereby the position of the inkstand can be adjusted to suit the quantity of ink which it contains. Mr Hoey has invented another stand of the mountain or reservoir type in which he provides means for preventing the overflow cause by numerous and well known difficulties He also provides means which will facilitate the filling of the reservoir.

### Heating and Lighting.

LAMP-SHADE HOLDER.—J CRUIKSHANK, Shamokin, Pa This invention relates to improvements in shade holders, and more particularly to a construction for facilitating the attachment of the shade holder to the socket of an incandescent electric light It avoids the use of screws, bolts, or other similar fastening members, and the necessity of relying entirely upon the resiliency of the metal.

BOILER.—J G HAYDEN, New Lexington, Ohio. The aim of the invention is to provide a boiler for use in heating water for dwelling houses and the like, which includes a burner especially adapted for the use of natural gas, which can be easily regulated to insure efficient combustion by means of which water can be readily heated and which is compact in form

WATER HEATER.—A F MILLAN, Mannington, W Va This heater comprises a stand pipe at the bottom of which any source of heat such as a common burner may be arranged. This pipe is surrounded by a casing at the top and bottom of which water connections are provided for the inlet and outlet of water to be heated The stand pipe forming the flue of the burner is corrugated radially to provide an increased radiating surface and to divide the water into a series of thin flues.

### Household Utilities.

BED-COVER SUPPORT.—E. D PEERSTONE, Chicago, Ill This invention pertains to a device, the purpose of which is to support the covers of a bed at the foot of the bed so as to relieve the feet from the weight of the bed clothes. The device is particularly useful as an attachment to the bed of an invalid, and it is also useful in summer to keep the feet cool

VENTILATOR.—R M HILL, New York, N Y This invention relates to ventilators adapted to be detachably secured to the window casing, so that the window may be opened a short distance to permit the entrance or escape of air, and, at the same time, to prevent direct drafts or strong currents, and to prevent the admission of rain, hail, snow, sleet and foreign bodies.

IRONING-BOARD.—ANNE M GARMAN, La Beau, S. D The intention here is to provide a main frame of clothes-horse, upon which clothes may be hung after ironing, and to this frame attach folding arms, provided with ironing boards and nets, in which the clothes may be placed before ironing One ironing board may be used for larger pieces such as sheets and table linen, while the other is used for smaller work.

HAIR-CURLER.—W M. WILLMAN, Mahanoy City, Pa. This invention is for use for curling the hair of women and children. The aim is to produce a device which can be readily applied when in practical use Instead of making the device of round cross section it may be made angular or square, so as to produce a wave effect in the hair

### Machines and Mechanical Devices.

PIPE-PULLING MACHINE.—C D SHORTS, Fern, Pa. The aim of this inventor is to provide a machine having an extensible mast which is adapted to fold down upon the frame of the device, the entire structure being mounted upon wheels, so that it can be readily moved to and from the localities of the oil or artesian wells.

PIANO-CASING.—F. REREK, New York, N. Y. [illegible] the improvement refers [illegible] is to provide a piano casing, having a mechanism for simultaneously opening or closing the front fall, the back fall, the panel and the top of the piano, on the operator pressing an auxiliary pedal.

COPY HOLDER.—B F PARTS, Moro, Ore. The object of this invention is to provide a copy holder in which the copy is automatically kept in the operator's sight while at the same time being securely held in a convenient position in such a manner that it cannot be blown about or otherwise disturbed A further object is to provide a holder which can be readily attached to the standard makes of typewriters without the necessity of dismantling the machines.

FILLING AND CROWNING MACHINE.—L. LITTY, Baton Rouge La This machine receives bottles of different heights Means provide for a charging cylinder to be brought into air tight engagement with bottles to be filled, and a gaged quantity of liquid to be delivered to the discharging cylinder and thence to the bottle placed to secure it and while filling a cap is placed in position to be carried over the mouth of the bottle, and on being filled the cap is carried over the mouth of the bottle and is crimped or clamped to the neck

FLYING MACHINE.—L. C. KINCANNON, Seabright, Cal. This machine is of the so-called rotary wing type It comprises two or more pairs of wings each pair being composed of six separate wings. The wings are mounted to revolve about an axis, and also caused to be intermittently rotated, so that for a portion of their travel, they will be in a plane parallel with the general plane or direction of motion of the machine

FISH SCREEN.—W B ERICKSON Salt Lake City Utah The purpose is to provide a self cleaning screen for use in hatcheries irrigating ditches, and any small stream and so placed and constructed as to effectively prevent fish from passing through the screen and meeting destruction when the water supply is diminished or cut off It also continually carries moss, leaves twigs, and all debris over the top of the screen and deposits them in the stream below, thereby preventing the backing up of any debris against the screen.

WASHING MACHINE.—J H BULLOCK Logan, Utah Specifically the improvement consists in the provision of a rotatable rubber mounted upon the lid or cover of the tub and adapted to engage the tub supporting standards, so that as the tub is oscillated the rubber is oppositely oscillated to effect the rubbing or cleansing action between the corrugated tub bottom and the rubber the latter having a rotatable part which facilitates this action

WELL-PUMP.—A N BLAZER Mescalero, New Mex. The object of the inventor is to provide a well pump adapted to be lowered into the well to any desired depth, and having spiral intersecting pistons rotating in unison in the intersecting bores of a pump casing the casing being open at the top and bottom and filling the well one of the pistons being driven from above ground so that the pistons named cause the water to be lifted to any height the water passing through the pump freely, and without spraying, whirling or abrupt deflection, thereby reducing the friction of the water to a minimum

CAR HANDLING MECHANISM.—A J LA FAYETTE, Jr., Pittsburg, Kan This invention provides means whereby loaded cars are automatically run upon an elevator cage used for hoisting in mine or other shafts, provides an automatic mechanism for delivering said cars to the cage, and for releasing any empty cars therefrom which may have been lowered with the cage, and provides a means whereby the functions of the mechanism are performed

STEAM TRAP.—G C ELLERTON Portsmouth, Va This invention pertains to improvements in automatic steam traps for the discharge of the accumulated water of condensation One of the objects is to provide a device in which the accumulated water can be discharged as fast as it enters the trap without the necessity of providing a by-pass.

### Prime Movers and Their Accessories.

ENGINE.—P O POULSON Brigham, Utah Mr Poulson utilizes two pistons within each cylinder and so connects these pistons that they will move simultaneously in opposite directions from the center The pistons instead of being connected to a crank shaft are connected by gears to a pinion on the main shaft, so that the movements of the pistons in opposite directions will simultaneously tend to rotate the shaft in the same direction. It tends to a large extent to eliminate vibration of the engine.

STEAM ENGINE.—E. GARST, Dayton, Ohio In the present patent the invention relates to single-cylinder reciprocating steam engines and the object is to provide a new and improved steam engine, arranged to insure an easy and uniform running under varying loads, and to allow adjusting of the engine according to the work and to cause the engines to run in either a forward or a backward direction

ROTARY ENGINE. D CONKLIN Tampa, Fla The object here is to provide an engine wherein a pair of pistons are geared together by means of the blades or vanes intermeshing, wherein the motive fluid is directed squarely against the operative face of the blades, and wherein the fluid will act on the blades with equal facility in either direction.

ENGINE.—J A DOWLING, Biloxi, Miss. In this instance the intention is to provide a new and improved engine, in which the motive agent is introduced between two pistons reciprocating in headless cylinders, to utilize the motive agent to the fullest advantage and to allow of compounding the engine in a simple and efficient manner

INTERNAL COMBUSTION ENGINE.—L F SLRADA, Denver, Colo. The object of the present invention is to provide an internal combustion engine more especially designed for use in tunneling and other machines, with a view to cause a cutting tool to deliver or strike blows on rocks or other material, without injury to the operating parts of the engine

### Railways and Their Accessories.

SIGNAL.—C P RUGGLES, Sedalia Mo. This invention relates more particularly to such signals as are adapted to be used in connection with the operation of railroads and which consist of casings having compartments and spring actuated, sectional targets arranged within the compartments, the former being adapted to assume an extended position for display when released from the compartments

MAIL-BAG CATCHER.—J A SCHINNER, Greenfield Ohio. The purpose here is to provide details of construction for a mail-bag catcher that adapt it for reliable service either to catch a mail bag and deliver it at the open door of a mail-car on a moving train or transfer a mail-bag from a train in motion to a station at the side of the track on which the train is moving.

RAILROAD-RAIL JOINT.—H NAALSFELD, Montello, Wis. This invention refers to means for connecting together the meeting ends of rails, and the purpose is to provide novel details of construction for the track rails of a railroad, which will effect a proper alinement of the rails and compensate for their expansion and contraction due to exposure to heat and cold.

CAR-FENDER J F CARRATHER Heath Mass. An object of this invention is to provide a car fender having a movable portion so that when a person is struck by the fender the movable part will operate to close the space between the ground and the normal position of the fender thereby preventing the fender from riding over the person and also serving as a protection to the wheels.

GRAIN-CAR DOOR.—J E FAUCETT Kenmare N D The main object of this improvement is to provide a door which may be easily opened after the car has been filled with grain notwithstanding the pressure exerted by the grain itself In fact the pressure of the grain upon the door facilitates the opening of the latter

REFRIGERATING-CAR.—J THORNTON and E. HEYMANSON, New York N Y The invention contemplates the use of refrigeration apparatus, such as ammonia machinery in which the cooling water for the condenser is kept at a sufficiently reduced temperature to do this work by a special construction and arrangement of the tank in which it is normally held, so that the surface of the tank is exposed to the rush of air developed by the motion of the car

RAIL-JOINT.—W H FRENCH, Evansville Ind In constructing this joint by which the jarring incident to the hammering of the wheels is substantially eliminated the adjacent ends of the rails are provided with a common transverse opening or slot in which are placed two curved plates with the concave faces of the plates facing inwardly and means tending to flatten and expand the plates to bind against the upper and lower edges of the opening

WRECK PREVENTER.—E B POOLE, Delmar Ala In the present patent the object of the improvement is the provision of a device capable of being attached to any locomotive or railroad car, and which will grasp a third rail beneath the tread thus effectually preventing the wheels from leaving the track

### Pertaining to Recreation.

CUE.—H MCCLEARY Washington, D C This invention is an improvement in cues for use in playing billiards and similar games and particularly in the tip holding devices for use on said cues. The construction is simple inexpensive, facilitates the application and removal of the cue tip and enables the substitution of a new tip instantly and without the aid of skilled labor

TOY PISTOL.—M J SHIMER, Bethlehem Pa. In this automatic pistol caps in the form of tape are fed under the hammer at each pull of the trigger and means retain the hammer and cap-feeding finger in position to enable ready insertion of the tape over the feeding plate and anvil when the tape is removed Means lock and unlock a cap chamber cover on its seat and return the hammer and the finger named when released and press it to the feed plate by means of a single spring

CONTAINER FOR FISHING APPARATUS.—J M ELLSWORTH Bernardsville N J This invention involves an improved container for use in carrying flies and their attached leaders used in fishing, and the object of the invention is to so construct the container that the flies will remain dry while the leaders and the connections between the leaders and flies will remain moist.

### Pertaining to Vehicles.

SPRING WHEEL.—A. B. Minkin, Idaho Falls, Idaho. This inventor has for his object the provision of a wheel wherein the loop or rim of the wheel itself is resilient or pliable so as to act in the capacity of a spring. In this way, the jars and jolts are taken up by the spring rim of the wheel and no other springs are necessary.

WRENCH.—J. T. Powers, Hot Springs, Ark. This invention is an improvement in wrenches. The wrench is especially designed for use in wagons for the wheel nut and efficiently serves the purpose for which it is designed. The cross bolt has a squared portion adjacent to its head and the opening receiving the said square portion is correspondingly formed to prevent the turning of the bolt.

AUTOMOBILE STARTER.—A. Smith, Brattleboro, Vt. The invention relates to starting devices for automobiles, by means of which the regular starting crank as commonly used may be dispensed with and the device may be operated by the driver without leaving his seat. The pedal may be locked in position by a latch which can be released only by retarding the spark lever to the proper point for cranking the engine.

ROAD-SMOOTHING DEVICE.—F. W. Lechner, Wenona, Ill. The device is adapted to be drawn over wagon roads, or by attaching them to ordinary vehicles or to vehicles especially designed for the purpose. This type was shown in a prior patent granted to Mr. Lechner. An object of the present patent is to provide a device which may be adjusted angularly to direct the dirt toward the center or toward the side of the road.

BRAKE-CONTROLLING DEVICE FOR BICYCLES.—H. Pinaudasse, Lyon, France. The device enables the rider to produce a graduated pressure of the friction brake upon the tire and thus control with ease the progressive movement of the wheel when coasting, and further the device is constructed so that slackness in the brake setting cable can be taken up at any time by an adjustment of parts and thus maintain the brake in proper condition for effective operation.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th, 1909, or will be sent by mail on request.

(12211) C. W. O. asks: I have a question that I wish you would answer through your paper. Where does the induction come in when you are standing at your telephone and can hear folks talking on other lines and from other towns? One can hear this when the lines run in opposite directions. The telephone companies here claim that it is the wires running along side by side for some distance, when in this case the sound of words spoken jumps across from one wire to the other. Now what I think about it is that it is at the central station. I notice at these places that they sometimes have put one ground wire to which they hitch all the lines that come into town. I hold the ground that this is where the most induction comes in. Am I right? Can this induction be heard if every line entering central had a grounding of its own before entering? Does it weaken a telephone system to be able to hear the talk on the same line all over the country? A. The cross talk in the telephone is ordinarily caused by the induction of electric currents flowing in wires near to the wire to which your telephone is connected. No sounds flow over the wires. Only electric currents pass from telephone to telephone. These cause a vibration of the receiver which you hear as a sound. These currents pulsate as waves around the wire which is transmitting them. These waves are very much like the waves which are used in wireless telegraphy, but are less intense. They can, however, affect a wire quite a number of feet away and cause a person to hear in his telephone what they are carrying to their own telephone. The process of thus affecting a wire with which the current has no direct connection is called induction. It is not necessary to call the ground wires into the case to explain the action. Such currents do not injure the instruments at all. They are very annoying when they mix up with what one is saying and prevent distinct hearing. They are prevented by the use of a metallic return circuit of twisted wire, as is done in all cities and large places.

(12212) F. E. W. asks: I desire to purchase a reliable hygrometer for indoor and outdoor use. What make of hygrometer would you recommend and where can it be purchased? A. All the so-called hygrometers are simply indicators, and are not scientific instruments giving a measurement of the humidity of the air. The instrument employed in the Weather Bureau consists of two thermometers on the same base, one having water constantly evaporating from its bulb, and the other having a dry bulb. These you can get through the Weather Bureau, Washington, D. C., and from tables you can determine the humidity correctly. They will not cost much more than the so-called hygrometers, and are reliable.

(12213) C. C. asks: If an air-tight tank one cubic foot square, made of material the same weight as water, were submerged to a depth of fifty feet in still water, what would be the pressure of the water on the two top sides, the two bottom sides, and the two ends, separately, the tank to sit with one edge up? What would be the pressure of the tank upward if released, and would the pressure diminish any the nearer it came to the surface? If so, at what rate? If you turn the tank flat on its side, would the pressure upward be as great? If not, how much difference? A. If a box one foot on a side is sunk in water, it displaces one cubic foot of water. Each side is a square foot. At a depth of fifty feet each side is pressed upon by a column of water one foot square and fifty feet high, which weighs about 50 x 62.5 pounds. As there are six sides, the total pressure on the box is six times the pressure on one side. It makes no difference how the box lies in the water, since the pressure under water is equal in all directions and perpendicular to any surface. The upward pressure of the water is greater than the downward pressure of the water by the weight of the water displaced, which is the weight of one cubic foot of water. This for fresh water is about 62.5 pounds, and does not vary with the depth. Now if the box is of the same weight as water it will not tend to rise or sink at all, but will remain at any depth at which it may be placed. This is in accordance with Archimedes's principle, which is given in all text books of physics.

(12214) D. R. asks: Will you kindly explain in inquiry column how the moon can complete one rotation on its axis in the same time that it makes a circuit of its orbit, all the while presenting the same hemisphere to the earth. I can readily understand it faces the four cardinal points of space in its circuit, but fail to see any indication of axial movement. A. Whether one considers that the moon rotates on its axis or not depends upon the point of view. As seen from the center of the earth, it does not rotate on its axis; as seen from the sun it does. Astronomers are agreed in considering the matter as if viewed from the sun, and all astronomers state that the moon rotates once in a revolution. It presents all points of its surface toward the sun each month. The moon really revolves around the sun in company with the earth. Its orbit is always concave to the sun, and moon and earth swing to and fro as they go, the center of gravity of the two moving around the sun in the ellipse which we speak of as the earth's orbit. You will find this in almost any astronomy. See Todd's "New Astronomy." If you will try a lamp and a globe as described in Todd's book you will see that you must turn the globe on its axis in order to keep it with the same face toward the lamp in the center as you carry it around the lamp.

(12215) R. S. asks: I am going to install electric lights in my farm home and use water power. I have a stream near my house that by damming I can get a fall of 10 feet. It has a flow of 125 feet a minute and will run a 6-inch pipe full and a little to spare the year round. I have been told that it will furnish about 4 horse power, and I believe that it would be an ideal power for lighting my home, a house of ten rooms. I am going to buy a direct current dynamo and the wires, etc., and wish to make my own water wheel. I inclose 40 cents, for which please send me four of your SUPPLEMENTS which in your opinion would be useful to me in making an overshot water wheel or a turbine. I am in a position to make either kind, for I have a workshop of my own. I am going to use a 1½ kilowatt generator and about 30 32 candle-power tungsten lights. You may use your own judgment in selecting these SUPPLEMENTS for me, knowing that you have had numerous calls like mine. Anything that will be of information to me will be thankfully received. A. We would advise that it is necessary to allow 1.7 horse power per kilowatt in small plants, so that your 1.5 kilowatt generator should have about 2.5-horse-power in the water wheel to drive it. The 32-candle-power tungsten lamps require 40 watts each, and thirty of these lamps will require 1,200 watts, which will call for a little more than 2-horse-power at the water wheel. If you will not require all the lamps at one time it may be that you can get along with 1 horse-power at the water wheel. You should therefore, have ample power even if we understand you correctly that the flow of the stream is only 125 cubic feet per minute. That quantity of water with a 10-foot fall will generate theoretically 2.37-horse-power, of which you should be able to obtain 80 per cent or better in actual useful work with an efficient Pelton or similar water wheel. From your remark, however, that the flow is sufficient to keep a 6-inch pipe running full, we should say that you probably have more power. One hundred and twenty-five cubic feet per minute represents the flow through a 6-inch pipe with a fall of less than 1 in 10, and if your pipe was placed with a sharper fall when you made the measurement, the flow may be greater than you suppose. If the pipe was placed with a fall of say 1 in 2, and ran full, the flow would be nearly 300 cubic feet per minute, giving you more than twice as much power, or if it ran full with a fall of 1 in 1, over three times the power.

(12216) C. W. S. asks: Will you please answer the following questions: 1. What metal or metal alloy has the lowest melting point? A. You will find a long list of fusible alloys in Kent's Mechanical Engineer's Pocket Book, which we send for $5 post paid. The one having the lowest melting point as given there is Darcet's with mercury. It is made of bismuth 50, lead 25, tin 25, mercury 250 parts, and is said to melt at 113 deg. F. Wood's alloy is made up of bismuth 50, lead 25, tin 12.5, cadmium 12.5 parts, and is said to melt at 140 deg. F. 2. Have any estimations been made recently on the speed of light, and also electricity? I saw in a certain paper a statement to the effect that light travels 192,000 miles per second and electricity 288,000, whereas I always thought they both traveled 186,500 miles per second. A. The speed of light and electricity through space is 186,300 miles. The best measurements are those of Michelson and Newcomb, described in our SUPPLEMENT No. 557, price 10 cents. You are correct in your idea that the two, light and electricity, come together from the sun. The number you quote, 288,000 miles, was given a good many years ago and was due to erroneous ideas about the matter.

(12217) T. H. says: Suppose the moon to be 240,000 miles from the earth in round numbers. Its orbit will then be 720,000 miles. The diameter of the moon being 2,000 miles, it would require 360 moons in contact side by side to extend around the complete circle of the orbit. Now as there are 360 degrees in a circle and 360 moons in contact would extend around the moon's orbit, why does it not follow that a diameter of 2,000 miles at a distance of 240,000 miles is just one degree? The astronomers say the moon really is from 28 min. to 33 min., or about ½ of one degree. I had as well say that I am aware that the moon is something over 238,000 miles away, is over 2,100 miles in diameter, that its orbit is an ellipse, and that Pi is not exactly 3 to 1. I have given round numbers for convenience. A. If the data regarding the moon were as you give them the results would be as you calculate, but since the data are not as you give them the results are too far from the actual to be of any value. The moon varies in its distance from the earth from 221,000 miles to 252,970 miles. The circumference of her orbit cannot then be calculated in terms of a circle. The mean diameter of the moon is 31 min. 8 sec., and this varies more than 2 min. This is found by direct measurement by astronomers with the micrometer eyepieces of the telescope. That is first-hand data. The moon's diameter in miles is 2,163, quite too much more than 2,000 miles to be put into round numbers in that way as a basis of a. Why does it not follow? It would follow as we said above, if it were so.

(12218) E. E. K. says: After consideration as to whom I could apply, I shall trespass upon your time to ask if no legal responsibility would attach to discomfort or danger through a passageway being "sealed up" (virtually) in a water-tight compartment on an ocean steamer. Fortunately I have no personal complaint of such to make, but my attention was called to it last year when some passengers found themselves so shut up at night, one of them (ladies) being ill. In this case they found a rambling exit up a small back stairway, and so emerged through the large dining room. Upon further consideration of the matter I scarcely think I am mistaken in supposing that some of these compartments with nine or twelve staterooms are completely cut off, even first class passengers. In the case of steerage I do not suppose life would be worth considering. I heard of one instance where a gentleman upon going down late found the only way to his berth through the ladder on the smokestack. In view of the awful possibilities and of the great stress laid upon free exits on land, this appears to me an important issue. A. Correspondents should observe the rule that street address, names of cities and States should be given in full, as otherwise it causes us much trouble. Your question is a peculiar one. Most of the modern bulkhead doors are kept normally open, and are only closed hydraulically or electrically when there is an accident, such as a collision or stranding. There are bulkhead doors above the water line which are to be closed by stewards in case of emergency. It is impossible to give any exact answer to your letter without knowing the boat. The mutilated diagram showing ship's cabins would not indicate that there were any bulkheads which were normally to be kept closed, although there appear to be several fire bulkheads for use above the water line. These doors would be kept normally open. We do not think you are well informed in stating that nine to twelve staterooms would be entirely cut off without access to a companionway. "Great attention is paid to the life of every passenger at sea, as will be seen in an important book which will shortly be issued, entitled the "Scientific American Hand Book of Travel," in which some thirty to forty pages are devoted to "Safety at Sea." One is as safe at sea as in a trolley car or railway car in this country. The writer is entirely familiar with steamers of all classes which are licensed to carry passengers, and he is unacquainted with any such condition as you outline.

### NEW BOOKS, ETC.

THE HUMAN RACE. Its Past, Present, and Probable Future. An essay by J. Samuelson. London: Swan Sonnenschein & Co., Ltd., 1910. Pp. xii + 192.

In the preface to his book Mr. Samuelson states that his aim has been "the embodiment of the experiences and results of an octogenarian." He outlines briefly the changes which have taken place in the nature, belief, and activities of mankind from the earliest period down to the present day. If the book has any fault it is that of dwelling too much upon the emotional, physical, and intellectual man. The few references to inventions to be found under the heading of "Man's Mental Progress" can hardly be considered so much an evidence of heightened mentality as of improvements in exterior conditions. The improvement of exterior conditions does not necessarily mean development of the intellect. The later phases of evolution and their influence upon mankind are not discussed, though it cannot but be admitted by every thinking man that the revival of Mendel's law of heredity and its application, as well as the modern views of eugenics, undoubtedly have their bearing upon this subject. On the whole, however, the book must certainly serve the purpose for which it was written, namely, that of "stimulating inquiry and serious study."

TASCHENBUCH DER KRIEGSFLOTTEN. Mit einem Anhange: Die Luftkriegsschiffe. XI Jahrgang 1910. Herausgegeben von Kapitänleutnant a. D. B. Weyer. München: J. F. Lehmanns Verlag. Price, $1.50.

Capt. Weyer's excellent handbook follows the general arrangement of his previous annuals. The remarkable development in the English, German and American fleets during 1909 are all accurately calculated. The most novel feature of this year's handbook is an illustrated appendix on the developments of aeronavigation in 1909, particularly with reference to the military and naval value of aero-locomotion.

INDIAN INSECT LIFE. By H. Maxwell Lefroy, M.A., F.E.S., F.Z.S., assisted by F. M. Howlett, B.A., F.E.S. Calcutta and Simla: Thacker, Spink & Co. London: W. Thacker & Co., 1909. 4to., 786 pp.

This is a manual of the insects of the plains of tropical India. It is beautifully illustrated and is a rather remarkable production to be printed in Calcutta. The subject is rather a special one and we do not feel competent to pass an opinion on it. The work seems to be a thoroughly scientific one and the plates are certainly very creditable. They are numerous and well executed.

LIGHT. By Richard C. Maclaurin, President of the Massachusetts Institute of Technology. New York: Published by the Columbia University Press, 1909. Price, $1.50.

During the winter of 1908-9 Dr. Maclaurin delivered a series of ten lectures before the American Museum of Natural History on the salient features of the modern theory of light. Written primarily for the intelligent man who lays no claim to scientific knowledge, but wishes to keep abreast of the scientific times, this book serves admirably to show how wonderfully the modern theories suit the facts down to the minutest numerical detail. The subjects treated are the following: Early Contributions to Optical Theory, Color Vision and Color Photography, Dispersion and Absorption, Spectroscopy, Polarization, The Laws of Reflection and Refraction, The Principle of Interference, Crystals, Diffraction, and Light and Electricity.

RADFORD'S GARAGES AND HOW TO BUILD THEM. Selected and compiled by William A. Radford. Chicago and New York: The Radford Architectural Company, 1910. Pp. 109, 55 designs. Price, $1.

This collection of garage designs contains many new, original, and artistic examples of up-to-date private and public structures for the housing of automobiles, and permits considerable latitude in the choice of material to be used in the construction. The various designs include the use of wood, brick, stone, cement, stucco, and concrete. The compiler, as president of the Radford Architectural Company of Chicago, and the author of various books on architecture and building, is well qualified for the work he has undertaken in the present volume. Many of the designs are of pleasing architectural novelty and are adapted to the various requirements of up-to-date construction, and the latest approved materials used in modern building practice. Nearly sixty different garage designs are illustrated, and the construction cost ranges from $200 to $6,000. By the [illegible]

the larger private garages, while the public buildings of this kind, equipped with the latest approved modern accessories and conveniences, run in cost from $8,000 to $11,000

The book also includes a useful section covering garage equipment and accessories. This division illustrates a number of novel and useful appurtenances for different purposes in the garage itself

TELEPHONOLOGY By H. R. Van Deventer, B.S., E.E. New York McGraw-Hill Book Company, 1910 Pp 586, 682 illustrations. Price, $4

The author is to be congratulated on preparing a very complete description of modern telephone appliances. It takes up the subjects in detail, explaining not only what the instruments are but how they are constructed, what repairs they are liable to need, and how to remedy the troubles that so frequently beset telephone systems. The book does not describe all types of telephones nor go exhaustively into the history of the telephone but is confined to the modern practical telephone and all instruments accessory thereto. The work is not entirely written by the author but contains in addition a number of special articles on various subjects written by experts in those particular lines. The book closes with a chapter on wireless telephony, thus bringing the subject up to date Of particular value to the telephone engineer are the remedies given for various switchboard and other troubles. The book is one which no practical telephone man can afford to do without

MAVER'S WIRELESS TELEGRAPHY AND TELEPHONY By William Maver, Jr Maver Publishing Company, 1910 8vo, 366 pp, 258 illustrations Price, $3.

A number of years ago the author of this book wrote an appendix to his "Encyclopedia of American Telegraphy" dealing with wireless telegraphy This appendix subsequently grew into a book and we have here the fourth edition which has now expanded greatly The first part of the book relates to wireless telegraphy and bringing the subject to date The second devoted to wireless telephony is possibly more interesting for the reason that the art of talking by means of Hertzian waves is still in its earliest infancy

ELEMENTS OF PHYSICS For Use in High Schools By Henry Crew Professor of Physics, Northwestern University Revised by Franklin T Jones, Teacher of Physics, University School Cleveland New York The Macmillan Company, 1909 436 pp, 367 illustrations

Experimental physics has become such a feature of the present day high school course that we cannot have books enough on the subject. The aim of the author in the present work is to provide the teacher with a textbook which will take up the subjects of mechanics sound, light heat and electricity, not disconnectedly but as a related series. The book was originally published in 1899 by Prof Henry Crew, but owes its present form to the work of Mr Franklin T Jones, who has arranged it particularly for the high school student The matter contained in the book furnishes the teacher with the fundamentals of physics so arranged as to be within the comprehension of the average pupil sixteen years of age.

THE CONQUEST OF THE AIR. The Advent of Aerial Navigation By A L. Rotch, S B, A.M New York Moffat, Yard & Co, 1909 12mo, 192 pp, 35 illustrations. Price, $1 net

Particular interest attaches to this book because of the excellent meteorological work done by the author at the Blue Hill Meteorological Observatory Some of this work is described in the opening chapter on "The Ocean of Air," which goes into the subject of sounding the air to find the prevailing air currents, air pressures etc. The book then commences with a history of aerostation and thus leads up to the latest types of flying machines. The author also gives us his ideas of the future of aërial navigation in the final chapter of the book

PRODUCER GAS FIRED FURNACES By Oskar Nagel, Ph D New York Published by the Author, 1909 8vo, 192 pp; 237 illustrations. Price, $2 net.

More energy can be obtained from coal when used in a producer gas plant than in any other way The increasing interest in this method of utilizing the energy of coal should make the present work of particular interest. The book gives detailed descriptions and practical illustrations of all kinds of gas fired furnaces and describes actual installations of furnaces used in chemical, metallurgical, iron, steel, lime, cement, glass, brick, and ceramic industries.

PRACTICAL TESTING OF ELECTRICAL MACHINES By Leonard Oulton, A.M I.E.E. and Norman J Wilson, M.I.E.E. New York Whittaker & Co., 1909. 16mo; 210 pp; 90 illustrations. Price, $1 40 net.

The various tests which are made on electrical machines are here presented in pocket book form for the convenience of engineers and students. The matter is, of course, somewhat condensed, but nevertheless the book is a practical manual adapted to supplement the standard textbook. It takes up tests on induction motors, alternating current generators, rotary converters and synchronous motors, also single phase railway motors. There are four chapters on direct current motors and generators. Altogether the book will be found most useful to the practical man as well as the student.

HIGH FREQUENCY ELECTRIC CURRENTS IN MEDICINE AND DENTISTRY Their Nature and Actions and Simplified Uses in External Treatments. By S H Monell, M D New York William R. Jenkins Company, 1910 8vo., 465 pp., 23 plates Price, $4 net.

The author describes in detail how he has used high frequency currents in medical treatment and dentistry, explaining in detail how he applies the treatment for specific ailments.

PRACTICAL ARMATURE AND MAGNET WINDING. By Henry C Horstmann and Victor H. Tousley Chicago Frederick J Drake & Co, 1909 16mo, 231 pp, 128 illustrations. Price $1.50

This book is intended for the practical electrician and aims to supply sufficient information about the theory of armature winding to enable him to understand the advantages of certain methods employed in actual practice and the necessity of certain precautions. The authors have aimed to eliminate all irrelevant matter and adhere closely to their motto to supply 'everything that is needed and nothing that is not needed'

THE CALCULUS AND ITS APPLICATION By Robert Gordon Blaine, M E. New York D Van Nostrand Company, 1909 12mo., 321 pp Price, $1 50 net.

The use of the calculus has come to be of such importance in engineering work and particularly in electrical work that it is necessary for many who were unable to take up this subject in college days to study calculus by themselves. The present work is well adapted to home study as it is written in a very clear style, the various steps being explained thoroughly and illustrated with examples. The book is primarily intended as a textbook for school use and is compiled from notes and examples prepared by the author for his own classes.

VON PFLANZEN ZWISCHEN DORF UND TRIFT Von Dr Ad Koelsch Stuttgart Kosmos, Gesellschaft der Naturfreunde, Geschäftsstelle Franckh'sche Verlagshandlung Pp 93 Price, 50 cents

# INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending March 22, 1910,**

**AND EACH BEARING THAT DATE**

[See note at end of list about copies of these patents ]

Acid, apparatus for the production of acetic M J & B R. Lysler 952 540
Aerial transportation, H Lago-Vlus 952,539
Air blast distributer, W J Hendryx 952 522
Air brake system, B. Farmer 952 704
Air compressor, K F Hallaudet 952,708
Air device for supplying compressed, L. Gall 952 709
Alarm apparatus, F Peace 952,710
Ammonium sulfate from gases, obtaining N Caro 952 580
Amusement apparatus, R. A Karr 952 673
Amusement device G A. Romqalst 952 843
Antimony compounds, making, P Hornmeck 952 701
Armor fabric, J A Zeman 952,859
Armor plate H. O Cowperthwaite 952 877
Automobile body convertible, R. E. Olds 952,578
Automobile emergency brake, M A. Wagner 952 851
Automobiles, non skidding device and climber for, E Kaltenbach 952,813
Bags, means for attaching valve strips to, F H. Ream 952 782
Bar See Harvester cutter bar
Bearing, roller, H C Berry 952 607
Bed and the like sofa, W Trufrock 952 635
Bed, invalid W B. Sterling 952,957
Bed movement, shifting rack, C Barker 952 973
Bed spring tightener, G H Elliott 952,730
Billiard cue tip A L. Buckland 952,600
Binder pamphlet, E A Sharp 952,471
Binder, pressed steel ledger L. B Dickerson 952,668
Binding hinge loose leaf A. S. Robertson 952 642
Blower fan, A. Mathis 952,983
Boilers, means for separating water from steam in steam, Mills & Irvine 952 821
Book manifolding J H Rier 952 658
Book rack E Oldenhoerst 952 879
Bottle stopper, C A Natt 952,698
Bow for apparel, C S. Clinch 952,730
Boxes, assembling and nailing form for H R. Walter 952,908
Boxes form for holding H B Walter 952,907
Bread holder and set A. G Laub 952,571
Braiding and plaiting machine F A Schmidt 952,850
Brake beams and bolsters, beam for A. F Rimler 952 581
Brake head and shoe, C H Williams, Jr 952 503
Brake mechanism R M Dowale 952,514
Brake operating mechanism J A & J A Schuchardt, Sr and Jr 952 759
Breeding box, stock O C Black 952,800

# Noteworthy Articles
## ON TIMELY TOPICS

Each number of the Scientific American Supplement costs 10 cents by mail.

**SEWAGE AND ITS DISPOSAL.** A review of modern methods. By H LEMMOIN CANNON SCIENTIFIC AMERICAN SUPPLEMENT 1551.

**ELECTRIC LIGHTING FOR AMATEURS** How a small and simple experimental installation can be set up at home. SCIENTIFIC AMERICAN SUPPLEMENT 1551.

**CHEMICAL AFFINITY.** Simply explained by SIR OLIVER LODGE. SCIENTIFIC AMERICAN SUPPLEMENT 1547.

**CASE-HARDENING.** By DAVID FLATHER SCIENTIFIC AMERICAN SUPPLEMENT 1547

**ELECTRIC IGNITION SYSTEMS.** A comprehensive article by H. W ROBERTS SCIENTIFIC AMERICAN SUPPLEMENT 1546.

**CONCRETE.** A general article on its merits and defects SCIENTIFIC AMERICAN SUPPLEMENT 1545.

**REINFORCED CONCRETE.** Some of its Principles and Applications with practical Illustrations, SCIENTIFIC AMERICAN SUPPLEMENTS 1547, 1548, 1551.

**ELECTRONS AND THE ELECTRONIC THEORY** are discussed by SIR OLIVER LODGE in SCIENTIFIC AMERICAN SUPPLEMENTS 1428, 1429, 1430, 1431, 1432, 1433, 1434.

**THE PANAMA CANAL** is described from the engineering standpoint in SCIENTIFIC AMERICAN SUPPLEMENT 1539.

**WIRELESS TELEGRAPHY.** Its Progress and Present Condition are well discussed in SCIENTIFIC AMERICAN SUPPLEMENTS 1425, 1426, 1427, 1386, 1388, 1389, 1383, 1381, 1327, 1328, 1329, 1431.

**HOW TO CONSTRUCT AN EFFICIENT WIRELESS TELEGRAPH APPARATUS AT SMALL COST** is told in SCIENTIFIC AMERICAN SUPPLEMENT 1363.

**SUBMARINE NAVIGATION.** An exhaustive review of the subject is published in SCIENTIFIC AMERICAN SUPPLEMENTS 1414, 1415, 1222, 1223.

**SELENIUM AND ITS REMARKABLE PROPERTIES** are fully described in SCIENTIFIC AMERICAN SUPPLEMENT 1430. The paper is illustrated by numerous engravings.

**THE INTERNAL WORK OF THE WIND** By S. P LANGLEY A painstaking discussion by the leading authority on Aerodynamics, of a subject of value to all interested in airships, SCIENTIFIC AMERICAN SUPPLEMENTS 946 and 947.

**LANGLEY'S AERODROME.** Fully described and illustrated in SCIENTIFIC AMERICAN SUPPLEMENTS 1404, 1405 and 1546.

**STEAM TURBINES.** Their Construction, Operation and Commercial Application. SCIENTIFIC AMERICAN SUPPLEMENTS 1306, 1307, 1308, 1422, 1400, 1447, 1370, 1372, 1521. The articles have all been prepared by experts in steam engineering.

**PORTLAND CEMENT MAKING** is described in excellent articles contained in SCIENTIFIC AMERICAN SUPPLEMENTS 1433, 1465, 1466, 1510, 1511.

**AERIAL NAVIGATION** Theoretical and Practical Discussions, Pictures and Descriptions of actually-built dirigible balloons and aeroplanes will be found in SCIENTIFIC AMERICAN SUPPLEMENTS 1161, 1149, 1150, 1151, 1404, 1405, 1413, 1455.

**THE TANTALUM LAMP.** A full illustrated description of a lamp having a metallic filament and burning at once without preliminary heating appears in SCIENTIFIC AMERICAN SUPPLEMENT 1523.

**THE WATERPROOFING OF FABRICS** is thoroughly discussed in SCIENTIFIC AMERICAN SUPPLEMENT 1523 by an expert.

**THE SPARK COIL, ITS CONSTRUCTION AND MAINTENANCE,** is the subject of a painstaking article in SCIENTIFIC AMERICAN SUPPLEMENT 1522.

**ELECTRIC IGNITERS FOR GAS ENGINES** are discussed in SCIENTIFIC AMERICAN SUPPLEMENT 1514.

**CARBURETERS,** a subject of immense importance to automobilists and the users of oil engines, is well treated in SCIENTIFIC AMERICAN SUPPLEMENT 1508.

**EPICYCLIC TRAINS,** which play an important part in toothed gearing, are ably described in SCIENTIFIC AMERICAN SUPPLEMENT 1524.

Each number of the Scientific American Supplement costs 10 cents.

## The Design and Construction of Induction Coils

By A. FREDERICK COLLINS

*Size 6¼ x 9¼ inches. 295 pages. 160 Illustrations. Price $3.00, postpaid.*

This work gives in minute details full practical directions for making eight different sizes of coils, varying from a small one giving a one-half-inch spark to a large one giving twelve-inch sparks. The dimensions of each and every part down to the smallest screw are given, and the descriptions are written in language easily comprehended.

Much of the matter in this book has never before been published, as, for instance, the vacuum drying and impregnating processes, the making of adjustable mica condensers, the construction of interlocking reversing switches, the use of complete wiring diagrams, the cost and purchase of materials, etc. It also contains a large number of valuable tables, many of which have never before been published. It is the most complete and authoritative work as yet published on this subject. The illustrations have all been made from original drawings which were made especially for this work. A large circular containing a full table of contents and samples of the illustrations will be mailed on request.

## Properties of Polonium.

BY PROF. B. BOLTWOOD.

Polonium was the first of the active substances separated from pitchblende residues by Mme. Curie. Various methods of concentration were devised by her with the result that preparations of polonium mixed with bismuth were early obtained many thousand times more active than uranium. Marckwald later separated from 15 tons of pitchblende about 3 milligrammes of intensely active material which he called radio-tellurium, since it was separated initially with tellurium as an impurity. By dipping a copper plate into a solution of this substance, he obtained a deposit of weight not more than 1/100 milligramme, which was far more active than an equal weight of radium. It was soon recognised that this preparation was identical with polonium, for it gave off the typical α radiation, and had the characteristic rate of decay of that substance. Unfortunately, Marckwald was not aware at the time of separation of the great importance of testing whether lead appeared as a product of transformation of polonium Before such an experiment could be made, the polonium had to a large extent been transformed.

Polonium is one of the numerous transition elements produced during the transformation of the uranium-radium series. It is half-transformed in about 140 days, emitting α particles during the process. Rutherford showed in 1904 that polonium was in reality a transformation product of radium itself. Radium at first changes into the emanation, and then successively into radium A, B, C, D, E, F, radium F being identical in all respects with the polonium directly separated from a radio-active mineral. When the radium emanation is allowed to decay in a sealed glass tube, the walls of the tube are coated with an invisible deposit of pure radium D, radium E, and radium F, but the amount of the last to be obtained in this way is far too small to be weighable.

The amount of polonium present in any radio-active mineral can easily be calculated. Since the radium and polonium (radium F) in a mineral are in radio-active equilibrium, the same number of α particles are expelled from each per second. Since polonium is half transformed in 140 days and radium in 2,000 years, the former breaks up 5,000 times faster than the latter The maximum amount of polonium to be obtained from a mineral is in consequence only 1/5,000 of the amount of radium. In 1,000 kilogrammes of pitchblende containing 50 per cent of uranium, there are present 170 milligrammes of radium The weight of polonium is about 1/5,000 of this, or about 1/30 milligramme. It is thus obvious that to obtain 1/10 of a milligramme of pure polonium, several tons of high-grade pitchblende must be worked up. The most natural source of polonium is radium D (radio-lead), which grows polonium and has a period of half transformation of about twenty years. Since polonium breaks up about 5,000 times faster than radium, its activity, weight for weight, should be about 5,000 times greater than that of radium. There is nothing surprising in this, for the radium emanation has an activity about 200,000 times that of radium, while radium A (period three minutes) must have an activity 400 million times that of radium itself. Since the radiation from polonium is entirely in the form of α rays, it is to be expected that the radiation from it would show chemical and physical effects identical with those observed for pure emanation, the only difference being that the products of the latter emit β and γ rays as well.

Apart from the interest of obtaining a weighable quantity of polonium in a pure state, the real importance of the present investigations of Mme. Curie lies in the probable solution of the question of the nature of the substance into which the polonium is transformed. This problem has been ... [illegible]

[illegible] Since polonium emits α particles, [illegible] its products of decomposition, as [illegible] all the other α-ray products, should [illegible] helium. The production of helium from a preparation of polonium has been observed by Rutherford and Boltwood (Manchester Lit. and Phil. Society, November 30th, 1909), and also by Mme. Curie and Debierne in their present experiments. Boltwood several years ago suggested that the end product of the radium series was lead, and has collected strong evidence in support of this view by comparing the amount of helium and lead in old radio-active minerals. Since polonium is the last of the active products observed in the radium series, it is to be expected that polonium should be transformed into helium and lead, one atom of polonium producing one atom of helium and one atom of lead. This point of view receives additional weight from consideration of the atomic weight to be expected for the end product of radium. Since in the uranium radium series, seven α particles, each of which is an atom of helium of atomic weight four, are successively expelled before radium F is reached, the atomic weight of polonium should be $7 \times 4 = 28$ units less than uranium (atomic weight 238.5). This gives an atomic weight of polonium of 210.5, and after the loss of an α particle, a final product of atomic weight 206.5—a value very close to the atomic weight of lead.

It is a matter of very great interest and importance to settle definitely whether polonium changes into lead. The evidence as a whole has long been in favor of that supposition. The outlook is very promising that the experiments of Mme. Curie and Debierne will settle this question conclusively. No doubt an interval must elapse to allow the polonium to decay before the final examination of the residual substance can be made.—Nature.

### The Revolving Safe.

The revolving safe is the latest advance of the safe industry in its continuous contest with the burglar, who, in the most recent times, has taken to working with the cutting burner, which, by means of an oxyhydrogen or oxyacetylene flame, can cut through the heaviest armored safe in a few minutes. The revolving safe makes the employment of the cutting burner absolutely impossible. It consists, as Technische Rundschau describes it, of a steel strong box, closed on all sides, of polygonal section, arranged to revolve on ball bearings, and inclosed in a spherical compartment, built of strong masonry and closed above and below with masonry, in such a manner that the steel strong box can revolve on its vertical axis, without coming in contact with the walls. In the inclosing masonry and in the strong box, doors are contrived, by means of which the strong box is accessible from outside, as long as it is not revolving, which would be the case for instance during the business hours of the bank in whose quarters the revolving safe is set up. At the close of business, both doors are closed, an electromotor, operated by a storage battery, is switched on and the strong box then revolves at a uniform rate of speed uninterruptedly until a predetermined period, to which a clockwork connected with the switching apparatus is set, when the moving mechanism is automatically switched off.

While in revolution, the strong box is absolutely unassailable. The electric motor and the storage battery are placed inside of the steel chamber, cannot therefore be tampered with from outside; any interruption of the revolution, no matter how effected, and any decrease in the speed of the revolutions, is announced at once, with the aid of alarm devices, and if the safebreakers should have succeeded, at any point, in breaking through the inclosing masonry, they cannot attack the [illegible] strong box, not even [illegible] burner, because, in con-

A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## PATENTS FOR SALE

PATENTS FOR SALE for Canada, Great Britain, Germany and France, outright or royalty. A lens drill for drilling lenses and other hard substances with steel points, works with wonderful rapidity with slight pressure and by hand or power. New ideas. Established success in the United States. Immediate manufacturer needed for Canada. For full particulars, address A. B. Mackay, Nanaimo, B. C.

Inquiry No. 9016. For manufacturers of "Wydt's Electro Catalytic Sparking Plug."

FOR SALE. U. S. Patent on "Jacks" Shoe Fastener. Shoes provided with this little device have the appearance of button shoes, but can be fastened and unfastened much more quickly and easily. No need of button hook. This new method of fastening has just been introduced in France and is rapidly becoming popular. Inventor wishes to sell his U. S. patent. Parties interested address Pierre Rousseau, 336 Washington Ave., St. Louis, Mo.

Inquiry No. 9007. Wanted the manufacturers of the Van Winkle, Woods & Sons and the Weber power meters.

FOR SALE—U. S. and Canadian Patent on cake mixing machine of original construction adapted for bakery and family use. A large field for an enterprising party. Address Fred Seifert, 561 Eleventh St., Oakland, Cal.

Inquiry No. 9011.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium tipped gold nib making for fountain pens.

INVENTOR of self-filling fountain pen desires selling U. S. and Canadian patent, without sack, fills barrel, simple construction, move rod to fill. Vogelmann, 38 Cooper Street, Brooklyn, N. Y.

Inquiry No. 9016. Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

FOR SALE. Double carnation support. U. S. Patents Nos. 904,071–918,071, is the very best on the market; can be manufactured at low cost; large field for it. Will sell account of other business, with complete machines. Very reasonable. Address O. A. Muller, Ambler, Pa.

Inquiry No. 9017. Wanted to buy silk machines from re-reeling, twisting, doubling to the final process of making it into clothes.

FOR SALE—A practical invention covered by U. S. and Dominion of Canada patents No. 918,462. Address John McLean, Box 536, Green Bay, Wisconsin.

Inquiry No. 9019. Wanted, catalogues and all information on machinery for braiding straw for manufacturing straw hats.

FOR SALE OUTRIGHT.—Ladies' Sanitary Belt. Retails twenty five cents. Vast profit. Article marketed. Splendid mail order medium. Have made for Patent eleven years to run. Strictest investigation. Arthur Lund, 110 W. 85th St., New York City.

Inquiry No. 9034.—Wanted the address of the Chipman Electric Purifying Co.

PATENT FOR SALE on royalty. Electric Safety Razor. It operates perfectly and eliminates all the objectionable features in the ordinary safety razor. Small and easily handled, without motor. Can be sold for $5.00 with a good profit. Address A. K. Ryerson, 1004 Lincoln Street, Evanston, Ill.

Inquiry No. 9042.—Wanted the address of Farney Safety Razor Co.

## HELP WANTED

WANTED—Organizers Fraternal Social Order of Owls, not insurance. Good commissions. John Talbot, South Bend, Ind.

Inquiry No. 9052.—Wanted, address of firms who install plants to manufacture nitrogen.

WANTED young man, technical graduate in physics and chemistry; knowledge of optics also desirable. Splendid opening and opportunity for right man. Address M. M., 116 Box 753, N. Y.

Inquiry No. 9055. Wanted address of parties interested in Ice Cleaning Machines.

## TYPEWRITERS

REAL REMINGTON $18.75—One machine only in new localities to secure desirable agent. Special agents prices supplied on all makes of typewriters. 3 ribbons $1.00. Standard Typewriter Exchange, 23 Park Row, New York.

Inquiry No. 9060. Wanted to buy machinery to manufacture seed corn racks.

## SITUATIONS WANTED

WANTED: Position as band, circular or gang saw filer in Michigan, Wisconsin or Minnesota. Expert; good; best references. H. Thomas, 21 Y. M. C. A. Block, Elgin, Ill.

Inquiry No. 9066.—Wanted complete outfit for export for making rice-flakes and wheat-flakes.

## SALE AND EXCHANGE.

FOR SALE.—Engine lathe. Our regular $75.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $65.00. L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9068. Wanted to buy machinery for manufacturing chewing gum, such as rolling, cutting or wrapping machinery.

## FOR SALE

TEN ORE SPECIMENS—Gold, silver, copper, iron, lead, zinc, tin, nickel, graphite, sulphur. Also interesting mineral bodies, 50c. John McLaughlin Co., Eng. Box 161-M, Sharpsville, Pa.

Inquiry No. 9069.—For the address of firm making chain cloth, something like ladies' purses are made of.

## FLYING MACHINES.

THE FUTURE FLYING MACHINE.—This machine is balanced automatically in the air, controlled by one steering wheel and carries 1 or 2 passengers. Is practical. Would like to form a company to manufacture them. If interested, address Ralph Cole, Norwalk, Ohio.

Inquiry No. 9071. Wanted, the address of parties making moulds for large concrete vases for flower pots.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9072. Wanted machinery for making fine chains, such as used by jewelers, etc.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9073.—Wanted, machinery to manufacture cocoanut oil; also the crude material.

Inquiry No. 9074.—Wanted, to buy old model locomotives or steamboats, such as were exhibited with nickel-in-the-slot attachments in ferry-houses, etc.

Inquiry No. 9075.—Wanted, to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted, the address of parties in Canada who could make a safety razor.

Inquiry No. 9077.—Wanted, the address of manufacturers that make small articles of wood, such as checker boards, etc.

Inquiry No. 9078.—Wanted, the address of manufacturers of sewer pipe, made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9079.—Wanted, parties to make a special steel plate rolled for "angle bars," in large quantities.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9081.—Wanted, manufacturers of a mixing machine, to mix powdered and fluid ingredients to a thin dough, also molds to put such dough in to dry; the size to be about 3½ inches long, 2½ inches wide and 1½ inches high, making the form of a cake like sapolio.

Inquiry No. 9083.—Wanted, the address of firms manufacturing small beer brewing plants, from 75 to 100 gallons a day.

Inquiry No. 9084.—Wanted, the address of manufacturers of Irwin portable bath tubs.

Inquiry No. 9085.—Wanted to buy longitudinal hollow perforated tubing.

Inquiry No. 9086.—Wanted, to buy a pine wood peeler.

Inquiry No. 9087.—Wanted, a machine for hardening back saw blades; also a machine for cutting same when they have been toothed.

Inquiry No. 9088.—Wanted, the address of manufacturers of family sized peanut pulverizers for making peanut butter.

Inquiry No. 9089.—Wanted, the address of manufacturers of galvanized steel perforated hollow tubing.

Inquiry No. 9090.—Wanted, manufacturers of suspender and supporters supplies, also patent adjustable bachelor buttons.

Inquiry No. 9091.—Wanted, parties to manufacture a new patented clothes hanger.

Inquiry No. 9092.—Wanted the address of some firm who manufacture permanent lamp wicks.

Inquiry No. 9094.—Wanted address of The Thomas Arithometer Company, also Burkhart Arithometer Company.

Inquiry No. 9095.—Wanted, name and address of the manufacturer of the duplex revolving pencil sharpener.

Inquiry No. 9096.—Wanted the address of manufacturers of spiral welded pipes, possessing great strength.

Inquiry No. 9097.—Wanted, address of makers of impulse water wheels.

Inquiry No. 9098.—Wanted name and address of the manufacturers of the ozonizer.

Inquiry No. 9099.—Wanted, address of manufacturers of machinery for making wire cables.

Inquiry No. 9101.—Wanted, addresses of manufacturers of a dip or magnetic needle, for exploring for iron ore.

Inquiry No. 9102.—Wanted, addresses of parties who will manufacture wafer safety razor blades.

Inquiry No. 9103.—Wanted addresses of concerns manufacturing composition materials to take place of hard rubber.

Inquiry No. 9104.—Wanted, addresses of manufacturers under the name of A. O. Co. Standard.

Inquiry No. 9105.—Wanted, manufacturers of cheap gums and resins.

Inquiry No. 9106.—Wanted, addresses of cotton dealers who can furnish cotton material for manufacturing envelopes.

Inquiry No. 9107.—Wanted addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

Inquiry No. 9108.—Wanted the addresses of manufacturers of cardboard.

Inquiry No. 9109.—Wanted addresses of the manufacturers of the Dion Desk Clock.

Inquiry No. 9110.—Wanted to buy machinery for reducing old tin cans, so that they may become a source of revenue.

Inquiry No. 9111.—Wanted to correspond with manufacturers who furnish nut-cracks, or similar articles.

Inquiry No. 9112. Wanted sample small dry vacuum pump about 6-inch diameter cylinder inside, high temperature metal packing.

Inquiry No. 9113.—Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

Inquiry No. 9114. Wanted name and address of manufacturer of the Auto Lantern Globe. Fits all lanterns.

Inquiry No. 9115.—Wanted a machine for making pen nibs similar to Wm. Mitchell's G. & J. nibs and Waverly nibs.

Inquiry No. 9116.—Wanted machines to make wire netting 6 inches wide by 50 yards long and for galvanizing the wire netting as it is finished.

Inquiry No. 9117.—Wanted names and addresses of the manufacturers of pedometers.

Inquiry No. 9118.—Wanted, a muffler for a gasoline engine, built upon the principle of the Maxim silencer, recently brought out for use on rifles.

Inquiry No. 9119.—Wanted, name and address of the manufacturer of Berlin bullet-proof cloth.

Inquiry No. 9120.—Wanted, the address of the Ideal Fowl Feeder Co.

Inquiry No. 9121.—Wanted manufacturers of oil stencils for fancy work, sofa pillows, etc. and oil colors and brushes for same.

Inquiry No. 9122.—Wanted, manufacturers of ditching machines used for tiledrains operated by horse power.

Inquiry No. 9123. Wanted, names of importers or dealers in crude gutta percha and rubber.

Inquiry No. 9124.—Wanted, name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

Inquiry No. 9125.—Wanted name and address of the Just-Hatmaker machine, for manufacturing milk powder.

Inquiry No. 9126.—Wanted, to buy machine for putting up and preparing condensed milk.

Inquiry No. 9127.—Wanted, address of L. Dagmigny, manufacturer of a family ice machine for $10.50.

Inquiry No. 9128.—Wanted, a hand planer, for metal working, in which the hand planer is made to be attached to any ordinary bench vise. The vise and the planer are combined to form only one machine.

Inquiry No. 9129.—Wanted, addresses of makers of machinery for paper box factories, of new or second-hand paper box making machinery.

Inquiry No. 9130.—Wanted, parties to manufacture a new patented shell for shot guns.

Inquiry No. 9131.—Wanted, information as to how or where I could get a sample of tin ore.

(Concluded from page 289.)
sequence of the continuous movement of the walls, the flame cannot be brought to bear against any one point in the armor plate long enough to melt it through.

### The Action of Radium Emanation Upon the Elements of the Carbon Group.

A lively sensation was created, two years ago, by the publication of Sir William Ramsay's experiments on the action of radium emanation upon copper. According to Ramsay, the energy released by the emanation causes a disintegration of the atom of copper, and converts that metal into elements of smaller atomic weight, which are included in the copper group, in Mendeléeff's classification. Ramsay claimed to have found, among the products of the action of the emanation upon copper, minute quantities of potassium, sodium and lithium. Madame Curie repeated Ramsay's experiments, but failed to obtain the same results, and pointed out certain possible causes of error in the method employed by the English physicist. Ramsay has since repeated the experiments, taking care to eliminate these possible sources of error, and has reached the same results and conclusions as before. He has lately extended his researches to certain elements of the carbon group (silicon, titanium zirconium, thallium and lead), which, if his hypothesis is correct, should be disaggregated by the action of the emanation into simpler elements of the same group, and especially into carbon.

The following method was employed by Ramsay and his collaborator Usher. From a solution of radium bromide containing 211 milligrams (about 3 grains) of the metal radium the emanation produced in the course of one week, together with the explosive mixture of hydrogen and oxygen which always accompanies it, was extracted by a pump. The total quantity of gas thus obtained amounted to about 25 cubic centimeters, and contained 0.0912 cubic centimeter of radium emanation, mixed with hydrogen, oxygen carbon dioxide and other gases. The hydrogen and oxygen were combined by explosion, reducing the volume of the gaseous mixture to ¼ cubic centimeter. This was collected in a small glass tube coated with fused caustic potash, which absorbed the carbon dioxide in the course of an hour. The residual gas was then introduced into a glass flask containing the solution which was to be subjected to the action of the emanation. The contents of the flask were left undisturbed for four weeks, at the end of which period the activity of radium emanation is completely exhausted. The gas was then drawn off and analyzed.

It was found to contain carbon dioxide invariably and carbon monoxide in some cases. The following table shows the quantities of carbon thus produced from various solutions by one cubic millimeter of radium emanation.

| Solution of | | Milligrammes of carbon |
|---|---|---|
| Hydrogen silicon fluoride | $H_2SiF_6$ | 0.518 |
| Titanium sulphate | $Ti(SO_4)_2$ | 0.982 |
| Zirconium nitrate | $Zr(NO_3)_4$ | |
| | | 1.071 |
| | | 0.873 |
| Thallium nitrate | $Th(NO_3)_4$ | |
| | | 2.930 |
| | | 0.968 |
| Lead chlorate | $Pb(ClO_3)_2$ | 0.102 |

Ramsay and Usher conclude that carbon is produced, in greater or smaller quantity, from all the other elements of the carbon group by the action of radium emanation. The elements of high atomic weight, with the exception of lead, which seems to be particularly stable, appear to be disaggregated more easily than the elements of low atomic weight. Experiments on elements of other groups are in progress, but those described above appear to prove beyond question that the atoms of the chemist can be broken up by the action of radium emanation.—Revue des Sciences.

## LIEUT. SHACKLETON

HOWEVER thrilling the average man may find Lieut. Shackleton's modest and self-effacing recital of the Antarctic hardships and triumphs of his brilliant expedition, it is to the scientist that the English explorer's character must assuredly appeal most strongly. No doubt the dare-devil courage of the Englishman, whose love of adventure has carried him into the heart of Africa, the wilds of Australia, and the mysteries of Thibet, enters largely into Shackleton's nature. How else could he have endured the numbing cold and the pangs of privation? But the sacrifices made during that famous expedition which brought him within actual sight of the South Pole are essentially scientific in character—comparable with the heroism of the man who exposes himself to the stings of disease-carrying insects, that mankind may know how best to protect itself against the ravages of yellow fever and the sleeping sickness. His modesty of demeanor and speech, his generous praise of those who accompanied him, his liberality in donating mineralogical and ornithological collections to our museums (collections made when the desire was strong to abandon them in the hour of weakness and hunger), and above all that unwillingness of his to appear as rival to Capt. Scott, his former chief, which has led him to postpone his own Antarctic plans so that Scott may have no difficulty in obtaining funds, are all characteristic of the unselfish scientist in whom the sense of personal importance is overwhelmed by the high ideals of the cause in whose furtherance he is engaged.

Scientific too in its purpose is the expedition that Shackleton has postponed in deference to Scott, for that expedition will be undertaken not primarily to reach the Pole, but to fathom the many mysteries of the unknown land fronting on the South Indian Ocean, and presenting many scientific and geographic problems for solution. By systematically exploring the coast around King William Land, a coast which has never been carefully studied from shipboard because of floating ice, he will probably determine once and for all whether there is any reason for questioning the claims made by Admiral Wilkes to the first discovery of the Antarctic Continent. Shackleton's sense of fair play, his sense of scientific justice, in other words, eminently fits him for this peculiarly delicate task.

The hearty recognition which Shackleton has accorded Peary for the discovery of the North Pole, coming as it does from a man who knows something of the rigors of polar exploration, ought to shame the Congress which refused national honor to Peary without proof of the North Pole's discovery. The doubt which has been foolishly cast on Peary's exploit by a congressman whose "farthest north" as one Washington correspondent phrased it, is the semi-tropical cold of Omaha, Neb., is more than extinguished by the cordial deference which Shackleton has shown toward Peary on the occasion of their many public meetings.

## A PLEA FOR CO-OPERATION.

THE development of rapid transit in New York city has reached a critical stage, for upon the events of the next few months will depend the question whether a certain proportion of future subway travel is to be paid for at the present rate of five cents per trip or at double that amount.

Now, it is generally agreed that one of the indispensable conditions of the future development of the subway system in this city is that the fare shall at no time exceed five cents, for which sum a passenger must be at liberty to travel from any one part of the system to any other. The universal tendency to-day is toward the cheapening of transportation, and the possibility of an increase from five cents to ten cents per trip is not to be considered for a moment.

Nevertheless, the people of this city are to-day confronted with the possibility, if not the probability, of just such an increase of fare, and this condition is due in large measure to the strained relations between the Public Service Commission, whose duty it is to safeguard the transportation interests of the public, and the Interborough Company, which has a practical monopoly of local transportation. The Public Service Commission will shortly call for bids for the construction of an additional subway extending from the Bronx to the Battery, which will be absolutely independent of the route which is now in operation. The new line as laid out would be an excellent one, were it not for the grave defect that nowhere does it make connection with the existing subway. This defect, however, must be made good by providing for such connections as will enable a passenger to travel for one fare from any point on the one to any point on the other system.

If we look at a map of the present subway route, it is evident at a glance that an extension of the existing lines north from Forty-second Street through Lexington Avenue to the Bronx, and an extension of the Broadway line from Times Square down Seventh Avenue to the Battery, would provide the city with two independent north and south routes. The Public Service Commission long ago recognized that this was the next logical addition to make to the present facilities, and they hoped that the Interborough Company would make a proposal for future extensions of their system over these routes. Unfortunately, the company, in offering to build these lines, has obstinately saddled its proposal with a demand that it be allowed to build a third track on one of the elevated railways of the East Side.

Now the city, as the Interborough Company very well knows, has established for all time the principle that, since the existing elevated structures are a defacement of the streets in which they stand, not only shall no further extensions be made, but as soon as other facilities are provided, the existing structures shall be removed. Therefore, the Public Service Commission at once and very properly refused to accede to the Interborough proposal, and, ostensibly, it is upon this question of extending the elevated service that the Commission and the company are at variance.

Failing to get any satisfactory proposal from the Interborough Company, the Commission have laid out an independent route which extends from Woodlawn and Pelham Bay Park in the Bronx to the Harlem River, and down Lexington Avenue and Broadway to the Battery. Bids will shortly be asked, and as we have noted above, unless the Interborough should put in a bid agreeable to the conditions laid down by the Commission, the new line will be built independently of the existing subway. Thereafter, if anyone should have occasion to make a trip involving a transfer from one system to the other, he will be able to do so only by the payment of an additional fare—a condition which for a large proportion of the traveling public would amount to a positive hardship.

Now the contingency of having to pay a double fare is so serious that it demands immediate and careful consideration. We believe that the exercise of a more liberal policy by the Interborough Company and the exhibition by the Public Service Commission of a little more confidence in the attitude and purposes of the Interborough people would result in a compromise of lasting benefit both to the corporation and the traveling public. The Interborough Company certainly owes much to the city, and we say this with full remembrance of the fact that Mr. Belmont, at a time when capital was looking askance upon the subway proposition, came forward courageously and provided the enormous capital necessary for construction. He has received in the past and always will receive credit for the good service which he rendered to the city in a very critical emergency. But having admitted this much, we cannot lose sight of the fact that events have proved, first, that the subway property is enormously profitable, and second, that the terms governing the relationship between the operating company and the city are very liberal indeed. If Mr. Belmont conferred a great benefit upon the city, the city has repaid him tenfold by providing the subway line with a traffic far greater than was anticipated when the road was built.

Now the Interborough, with its magnificently equipped system, its thoroughly trained personnel, its strong financial standing, and its rich accumulation of operating experience, is obviously the interest best equipped to build and operate the new line, making it an integral part of its present system. Provided it will give reasonable guarantees, the city would just as soon, and perhaps rather, have the Interborough people build and operate the new system than any other outside interest. Unfortunately, the attitude of the company toward the city in the past, as shown in its almost contemptuous treatment of the Public Service Commission, has had the inevitable effect of producing a feeling of distrust, if not of hostility, against the company on the part of the public. This [illegible] tunate, unnecessary, and, to those of us wh[illegible] stand what a really magnificent service, ju[illegible] least from the technical side, the company is [illegible]ing, it is to a certain extent unjust.

The present juncture affords a great opportunity to the Interborough Company. If it will only waive its never-to-be-granted demand for further elevated railway facilities, the city will meet the company in a liberal spirit. Should the company put in a bid for the new line, with a pledge to operate it as part of their existing system upon a single-fare basis, they will solve at once the problem of the present congestion on their own lines, they will more than double the extent of their already enormously profitable field of operations, and they will place themselves once more on a basis of amicable relationship with the people of this great city—a consideration, surely, which will not be the least weighty of those above enumerated.

## A REFORM IN METEOROLOGICAL UNITS.

IN common with the other sciences, meteorology is burdened with a dual system of units. Great Britain and America continue, in a majority of their meteorological publications, to record rainfall and atmospheric pressure in inches, wind velocity in miles per hour, and temperature in Fahrenheit degrees, while all the other nations have long since adopted millimeters, meters per second, and Centigrade degrees for the same respective measurements. There have of course been many projects of reform, but only very lately has uniformity actually been attained in any branch of the science.

The United States Weather Bureau and the British Meteorological Office have definitely adopted the metric system and the degrees of the Centigrade temperature scale for recording the results of the observations made with kites and balloons—the former at its research observatory at Mount Weather, Va., and the latter at several "aerological" stations now in operation in the British Isles.

The British have gone a step further. The temperatures met with in the upper air are very frequently below the freezing point, so that the tabulated observations expressed in the Centigrade scale, abound in negative values, which are awkward to deal with and also a fruitful source of errors in computation. The *absolute scale*, counting in Centigrade degrees from the absolute zero (−273 deg. C.) has no negative values, and the use of this scale is now common in the discussion of many physical problems with which upper-air research is closely concerned. For these reasons the Meteorological Office has begun using the absolute scale (also called the Kelvin scale) instead of the ordinary Centigrade scale in all records of temperature obtained by means of kites and balloons. A no less radical reform has been introduced in the publication of barometric pressure, in the same class of British observations. The unit adopted is a C. G. S. unit of force, viz., the megadyne per square centimeter, in place of the familiar units—inches or millimeters—expressing the height of the mercurial column. As a matter of fact, the "mercurial column" is a pure fiction, so far as the observations in the upper air are concerned, the barometers attached to the kites and balloons always being aneroids, and it is much less important to know the height of this imaginary column at any level than to know the fraction of the atmosphere that lies above or below the level. This fraction is directly indicated when the C. G. S. unit is employed, since 1 megadyne per square centimeter is practically equivalent to a barometer reading of 750 millimeters, in latitude 45 deg., which is the average pressure of the air at 106 meters above sea level in the same latitude. Hence, if we assume 106 meters above sea level as the plane of reference in barometry (and there are sound reasons for preferring it to sea level, the plane heretofore in use), the C. G. S. unit may be considered a "C. G. S. atmosphere," and the fraction of a megadyne per square centimeter recorded at any latitude gives, for all practical purposes, the fraction of the atmosphere that lies above the point of observation. This unit has been named the *bar*, and its use in all meteorological observations has been recommended by several writers during the past year.

Lastly, the Meteorological Office is now, in its kite and balloon work, recording the direction of the wind in degrees of a circle, counting from true north. East is 90 deg., south 180 deg., west 270 deg., and north 360 deg.

---

It is proposed to establish a wireless telegraph station at the meteorological observatory on Mount Mirador in the Philippines, to give warning of typhoons to vessels in the China Sea and points along the China coast. A similar station will probably be established later at Santo Domingo de Basco on the Island of Batan, for communicating information of the presence of typhoons in that vicinity to the headquarters of the Philippine Weather Bureau at Manila.

## ENGINEERING.

The grand total of canal excavation at Panama during February was 2,662,995 cubic yards, of which 1,779,486 cubic yards was dry excavation, done principally by steam shovels. The amount taken out by the French during their occupancy of the canal was about 78,000,000 cubic yards. Under American occupation, from May 4th, 1904, to February 28th, 1910, over 100,000,000 cubic yards have been removed, leaving 74,497,000 cubic yards of excavation to complete the canal.

It is inevitable that the New York Central Railroad's huge excavation for its new station yard will be ultimately covered with buildings. An earnest of this is found in the fact that contracts have been signed for the construction of two large buildings, each of which will cover an entire city block, the new structures to face on Lexington Avenue, and to be supported on the heavy steel columns of the depressed station. The buildings, which will be known as the Merchants' and Manufacturers' Exchange, will contain 1,300,000 square feet of floor space

The contribution of Australia and New Zealand to the British Imperial Navy will consist, in each case, of a cruiser-battleship of the same type, but larger than, the "Inflexible," which was present at New York during the Hudson-Fulton Celebration, together with three 5-000-ton, 26-knot scout-cruisers, six torpedo-boat destroyers and several submarines. Each cruiser-battleship will cost about $9,000,000, and each fleet unit about $20 000,000 They will form an integral part of the British Navy, and will be subject to the regular naval orders.

The Committee on Electrification of the New York Railroad Club, after a year's study of the subject, reports that no general information is available on the basis of which steam railroads as a whole would be justified in electrifying *terminals* or main lines *solely* on the ground of economy They consider that more attention should be given to the possibility of electrification in connection with heavy grades, and that it is necessary to proceed with caution in attempting the electrification of large freight terminals, which necessarily involve the traffic of a number of different roads

The Committee on Wood Preservation, in a report delivered at the annual meeting of the American Railway Engineering and Maintenance-of Way Association, states that the average results of tests of Douglas fir indicate a decrease of the modulus of elasticity of from 10 to 15 per cent for creosoted timber, as compared with untreated timber, and a decrease of about 30 per cent in the outer stress at elastic limit and at failure. Creosoting appears to have little effect on Douglas fir in tension or end compression, but it does weaken it from 20 to 25 per cent in shear Tests with other timbers show, as a rule, corresponding decreases in strength as the result of creosoting

In protesting against the granting of any further vault rights under sidewalks to owners of buildings along the principal streets of the city, the Public Service Commission has drawn attention to a most important subject. Such encroachments interfere greatly with the laying out of new subways, particularly beneath the narrower thoroughfares which are found in the lower portions of the city The commission states that in Manhattan the practice of spreading foundations beyond the building line has already gone so far that much needed space in the streets has been taken, and that if the city enforced its legal rights, the foundations of some of the large buildings would be affected

It is gratifying to learn that the latest battleships of the United States Navy are not only living up to their contract speeds, but in recent 4-hour trials under full power at forced draught have even exceeded the original contract performance. The latest instance of this is the case of the "Louisiana," which, according to a dispatch to the Navy Department from Rear Admiral Schroeder, recently on a 4-hour full power trial maintained an average speed of 18.942 knots, and this in spite of the fact that she drew about 16 inches more water with about 1,000 tons greater displacement than on her contract run. The "Michigan" also made 19 42 knots, which is about a knot above her contract speed.

The recent frightful accident near Green Mountain, Iowa, in which forty-seven lives were lost through the telescoping of two wooden railway cars, again draws attention to the danger that lurks in wooden construction when the cars are subject to the crushing and telescoping effect of a collision. The heavy train of thirteen coaches was drawn by two locomotives which were running tender first. The foremost tender jumped the track in a railway cut, and the engine, swinging around, became tightly wedged, causing the huge momentum of the train behind to be expended in telescoping into each other the day coach and smoker in which the fatalities occurred Had the cars been of steel the fatalities would probably not have been one-fourth as many.

## ELECTRICAL.

An electric elevator has been installed in the stairway which leads to the cupola of St. Peter's Church in Rome. The elevator has a capacity for carrying ten persons. It bears an appropriate Latin inscription

A new combined electric and steam cooking range has recently been patented which is particularly adapted for use in hotels. The range is divided into two compartments one of which is heated by steam, while the other is electrically heated The latter is used for cooking, while the steam is used for heating the ovens It is claimed that in this way a steady supply of heat is obtained very economically

The Brooklyn Rapid Transit Company recently changed the form of brake used on its cars, adopting a "graduated release, quick-recharge" type In order to teach the motormen the best way of using the new brakes, an air-brake catechism has been issued, and lectures have been given on the subject In the mean time a text-book is being prepared showing in detail how the brakes are arranged and how they should be used

The Berlin police department is provided with an extensive typewriting telegraph system. There are about 200 receiving stations throughout the city and suburbs. The sending instrument is provided with a keyboard, and when the keys are depressed they cause the message to be printed simultaneously at the sending station and at the receiving station The object of this system is to do away with the confusion of the Morse code. If the Morse code were used, it would have to be transcribed before a message could be put in the hands of the officer to whom it was sent.

A series of experiments was recently made at Johns Hopkins University to determine the dielectric strength of air It was found that the point at which a brush discharge occurred is only slightly affected by the moisture in the air From dry air to saturated air there is a drop in voltage of the discharge of less than 2 per cent. An increase of temperature from the freezing point to 40 deg Cent. caused the lowering of voltage by about 3 per cent Very curiously it was found that the size of the conductor materially affected the ionization of the air

An investigation into the conductivity of electric insulators was recently discussed in the Physikalische Zeitschrift. It was found that hard rubber is greatly affected by light, particularly ultra violet rays and that gutta percha is similarly affected though not to the same degree Chemical action appears to take place on the surface of the insulator, which produces a conductive coating Sealing wax and paraffine are also affected to a degree by light, but they are more subject to breakdown because of moisture The conductivity of wood is to a far greater degree increased by moisture Glass makes a very erratic insulator the same rod of glass may have parts that differ materially in conductivity The investigation also brought out the fact that the insulating qualities of all insulators decrease with an increase in temperature

About a month ago one of the Edison storage battery cars was placed on the Twenty-eighth Street crosstown line as an experiment The car has been in constant operation since and has required no alterations or repairs other than are common to the ordinary street car It has proved remarkably economical in the consumption of power Instead of costing two cents a mile as was at first stated, the actual cost of the car has been less than half a cent—0 43 cent to be exact. It costs more to start and stop the car than to keep it running, and it was supposed by practical street railroad men that when the car was put into active service on congested streets, the cost of running it would far exceed the estimate made by the builders So satisfactory have the experiments with this car proved, that an order has been placed with the Edison Company for sixteen more to be used on the Twenty-eighth Street crosstown line

A decidedly novel wireless telegraph detector has recently been invented by Prof Rossi of Turin It depends upon the torsional vibration of a fine iron wire, which is acted upon by magnetic lines of force that have a spiral direction The wire is stretched close to two permanent magnets with like poles adjacent, and is also placed in the center of a coil through which current is passed that sets up a helical flux When the current through the coil is rapidly alternated the wire vibrates circularly, that is, it has a reciprocal rotary motion At the center of the wire is a mirror which reflects a beam of light on a screen The vibration causes the light to spread out into a line whose length depends upon the amplitude of the vibration When connected with an antenna, the oscillatory currents set up therein cause variations of the vibratory movement of the wire. The wire has a natural period of torsional vibrations, and this being known it is possible to attune the instruments at the transmitting station to produce a maximum effect on the screen.

## SCIENCE.

Mr. Henry Wilde, F R S of Alderley Edge, is providing Oxford University with funds for the institution of an annual lecture as a memorial of Halley

A monument to Horace Wells was unveiled on March 7th in the Place des Etats Unis Paris Wells was born in Hartford Conn, in 1815 and was a pioneer in the use of nitrous oxide gas in dental operations. He committed suicide in New York in 1848

We have read somewhere that Peter the Great, when he was staying in England, had a particular liking for the companionship of Halley, and that after carousing with him at Deptford one evening he wheeled him in a barrow through a yew hedge and did such damage that he had to pay handsome compensation to John Evelyn the owner which incident shows that Shakespeare was right in thinking that not every astronomer plucks his judgments from the stars

Gold is usually classed among the metals which are soluble only in aqua regia, i e a mixture of nitric and hydrochloric acids It has been observed, however, that hydrochloric acid alone is able to dissolve gold, in the presence of certain organic compounds, which are here arranged in order of activity Methyl alcohol, amyl alcohol chloroform ethyl alcohol, chloral hydrate, phenol (carbolic acid) cane sugar glycerine trioxymethylene, formaldehyde The solution takes place slowly in the cold, but is accelerated by heating

The Meteorological Office at London and the Deutsche Seewarte at Hamburg carried on jointly in February March, and April of last year and again in August and September, an elaborate investigation with regard to the use of wireless weather reports from vessels in weather forecasting The co-operation of the principal British and German transatlantic steamship lines was secured, and each of their steamers sent reports twice daily while they were within a prescribed zone of the ocean The net result of these experiments was that a majority of the reports arrived too late to be of any service to the forecaster It appears unlikely that the meteorological institutes will feel encouraged to take any further steps in this direction until the delay in transmitting messages from ships to shore stations is much reduced The Seewarte has announced that of the messages received promptly enough to be utilized by the forecaster during August and September, none led to any modification of the forecast as based on reports from land stations, but it is admitted that this might not have been the case with a different disposition of the weather conditions over the ocean

The Austrian State sale of radium has been entrusted to the "Bergwerks-produktenverschleiss Direktion" in Vienna, under the control of the Austrian Minister for Public Works The radium is sold in the form of radium barium chloride of three different grades the price for each milligramme of radium chloride, including the containing cell, being 400 kronen It is packed in cylindrical cells of 21 milli meters diameter and 9 millimeters long, formed of nickel plated brass On the bottom of the cell a layer of lead is cast, in which is a square depression for the reception of the radium barium chloride The cell is closed by a mica plate held in position by the screwed on upper part of the casing On the bottom of the casing is an official stamp (an eagle) and the series number Radium cells sealed with lead and stamped on the soldered part, are also supplied The cells are packed in cotton and sheet lead in a small box, together with a certificate bearing the number of the cell and the weight and radium-content of the preparation The boxes are sealed with strips bearing the numbers of the cells, and are despatched by post as registered packets at the cost and risk of the purchaser

Upward of twenty different systems of storm signals are at present used by the maritime countries of the world A uniform international code is a desideratum, and the task of devising one was intrusted by the International Meteorological Committee to a small commission which met in London last summer and agreed to recommend to the committee the adoption of a code proposed by Prof Moore chief of the United States Weather Bureau This code substitutes a few simple combinations of the large conical symbols now used at a majority of the European ports for the storm flags heretofore used in the United States and some other countries Combinations of red and white lanterns are to be used at night to convey the same information as the day signals The proposed code has not yet however been formally adopted by any government, pending the decision of the International Meteorological Committee which meets in Berlin next September Since the London meeting objections have been raised by the German authorities to the proposed night signals on the ground that they are not sufficiently distinctive and might be confused with other harbor lights. The Deutsche Seewarte at Hamburg is now experimenting with several systems of night signals and will lay the results of its investigations before the committee

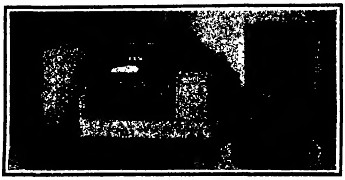
# TIMING AN AUTOMOBILE RACE

## AN AUTOMATIC INSTRUMENT THAT TAKES THE PLACE OF A STOP-WATCH

Even the casual reader has no doubt observed that automobile records are now expressed in hundredths of a second, whereas but a few months ago it was impossible to obtain any greater precision than fifths of a second, all of which indicates that the use of the time-honored split-second stop-watch has been outgrown in automobile races. When one stops to think about it, it is really absurd to try to time an automobile traveling anywhere from a mile to two miles and over per minute with an indicator that crawls at a snail's pace around a dial but an inch and a quarter in diameter. In the recent race at Ormond, for instance, where the mile record was reduced to 27.33 seconds by Barney Oldfield, he was traveling nearly 200 feet each second, which is equivalent to the length of an ordinary New York city block. When automobiles were first used for racing purposes, they were timed by hand with stop-watches. But, wherever an operator is depended upon to snap a stop-watch, inaccuracies are apt to creep in due to the fact that one person is quicker of perception than another. The timer must see the start of the race, and as soon as this impression is received must start his watch, then at the close of the race the same operation must be undergone to stop the watch. The time required for this mental and physical operation varies in different persons, and is known as the personal element. Not only does it vary with different persons but with the same person at different times, depending upon his mental and physical condition. For this reason, even in the timing of foot races it was long ago found necessary to have three timers and to take the time of the middle watch, for the instruments of the three timers varied as much as three-fifths of a second.

Early in the history of automobile racing an effort was made to eliminate the personal element by having stop-watches snapped automatically by the cars themselves making or breaking an electrical contact when they crossed the starting and finishing tapes. But, as we have just pointed out, even with the personal element eliminated, stop-watches are entirely too slow to record the time of so rapidly moving an object as a racing automobile. The experiment of using a chronograph was tried in several of the races last year, but as this did not prove very satisfactory, Mr. C. H. Warner of the Warner Instrument Company determined to make a special instrument particularly adapted for this purpose. This instrument was first used at Atlanta last December, and has just been employed for timing the Ormond and Daytona races. It works with the utmost precision, is entirely automatic, and makes a printed record of the race, reading to hundredths of a second. The necessity of such great refinement of timing will be appreciated when one considers that the "Lightning Benz" during its record mile run was traveling at the rate of 21.18 inches at every hundredth of a second.

Mr. Warner's instrument consists of four type wheels, one of which indicates hours, the next minutes, the third seconds, and the last one-hundredths of a second. The wheels are operated after the manner of an odometer instrument. Over the wheels runs a strip of paper and above that a typewriter ribbon, and a record is made by a hammer actuated by an electro-magnet, which strikes the ribbon and paper against the type wheels. In the circuit of the magnet which operates the hammer is a relay switch controlled by an electro-magnet in a circuit that is normally closed. This closed circuit is connected with the starting and finish tapes, or with tapes at other points where it is desirable to record the time. The tape consists of a wire stretched across the course at a height of a few inches above the ground and this wire is connected to a switch ingeniously constructed to be opened by the shock, rather than an increase of tension when the wire is struck by the wheels of an automobile. When the switch opens the instrument prints a record. The type wheels are frictionally mounted on a driving shaft, which is rotated by an electric motor. At the start of the race they are held stationary, and are not released until the starting wire is depressed, when they print zero and they begin their revolutions. The hundredths wheel makes a revolution every two seconds.



**An instrument that times races to hundredths of a second.**

Obviously, the most important part of the instrument is the regulation of the electric motor which drives the type wheels. It is impossible to construct a motor so perfect or a storage battery that will discharge so uniformly, that there will be not the slight est variation in the rotation of the driving shaft. However, the instrument is so arranged that at the end of every second its speed is automatically checked up with an accurate chronometer. At one end of the driving shaft is a double-armed lever, and in the path of this arm is a small catch connected with the armature of an electro-magnet. The chronometer acts through a relay circuit to energize this magnet every second, thus moving the catch out of the path of each arm of the lever. The motor is regulated to turn the shaft ever so slightly faster than one turn in two seconds, so that each arm strikes the catch just an instant before it is withdrawn. Secured to the base of the instrument at one side is a little "telltale" indicator, forming the armature of an electro-magnet. The circuit of the magnet is closed whenever the arm and catch contact, thus giving the "telltale" a slight throb every second. The operator of the instrument watches this "telltale," with one hand on the governor of the electric motor, and if the "telltale" indicator lingers too long at each contact of the arm and catch he slows up the motor a trifle, whereas if the "telltale" fails to register a contact he speeds up the motor slightly, so that the arm will strike the catch just before or at the moment that the catch is withdrawn by the chronometer. In this way a very accurate check is kept on the timing of the motor, which can be regulated to within 1/1,000 of a second of the speed of the chronometer.

**Switching in the instrument as a car is approaching the tape.**

In order to avoid a false start due to a person's walking against or tripping over the tape lines, the timing instrument is cut out of circuit with the starting lines until just before an automobile is about to touch them. An assistant gives a signal to the operator of the instrument at the proper time, and he throws in a switch just in time to catch the record of the automobile. At the same time the assistant calls out the number of the automobile, which the operator enters on the paper strip alongside of the registered time. When the car reaches a distant wire, the fact is communicated to the operator's assistant by telephone. It will be observed that no personal element whatever enters into the recording of the time made by the machines, and that everything is automatic except the regulation of the speed of the motor and the entering of the automobile numbers opposite the records they have made.

One of our photographs shows Barney Oldfield in his "Lightning Benz" just as he is approaching the finish line. The other photograph shows Mr. Warner in the timing stand about to take the record of the approaching car.

**Barney Oldfield approaching the finish line at the end of his record mile run.**

**TIMING AN AUTOMOBILE RACE.**

### To Remodel the House of Representatives.

Because the acoustics of the House of Representatives are so bad that it is almost impossible for the Speaker to hear a member of the House, unless that member has lungs of leather, plans have been drawn and all preparations made for a transformation of the lower house of Congress.

For many years now there has been trouble in the House both in the way of acoustics and with ventilation. For such a large body, these two principal features have not been as they should be. The plans in contemplation will remedy these defects, and make the House one of the finest legislative chambers in the world.

One of the main ideas to be put into execution is the reducing in size of the chamber. In this way it is thought that with smaller quarters, doing away with some of the galleries, and by narrowing the chamber, the acoustics will be all that could be desired. The ventilation will also be arranged to better advantage.

The plans as contemplated also bring the House of Representatives in the same fashion as the British House of Commons. In this manner benches and small shelves will take the place of the desks and easy chairs now used by the members. The benches will resemble in appearance the chairs used in theaters. By taking away the desks and easy chairs, it is thought that those members not interested in the debates or speeches will absent themselves from the chamber.

The floor of the present chamber has an area of nearly 8,000 square feet. The floor plan of the proposed hall will only be about 6,200 square feet. The seating capacity of the new hall will be 430, although there are now less than 400 members of the House.

Some of the lobbies and extra rooms will be cut out, and the reduction in size of the hall will, of course, result in the reduction of the public galleries, whose seating capacity will be reduced about one-third.

Owing to the peculiar conditions of the hall, with regard to the acoustics and ventilation, many members while away their time by conversing with each other in loud tones or add to the confusion by slamming their desks or kicking the cuspidors. Experiments are being made now for a noiseless cuspidor and one which cannot be kicked around.

Congress has already appropriated over half a million dollars for the transformation, and the workmen are waiting for the adjournment to begin operations.

# A FINE LONG-SPAN MASONRY ARCH BRIDGE

BY OUR ENGLISH CORRESPONDENT

There has been erected on the new Bellegarde-Chézery electric railway in France a masonry bridge which in span and height ranks as the largest of its type in the country, and which possesses many interesting features. The bridge is situated in the Department de l'Ain, and is in close proximity to the frontier of Switzerland in the canton of Geneva. This imposing structure was designed and erected under the supervision of Monsieur Picard, engineer in chief of the Bridge Department, to whose courtesy we are indebted for the accompanying illustrations and details, and Monsieur Dor, road surveyor in chief of the department.

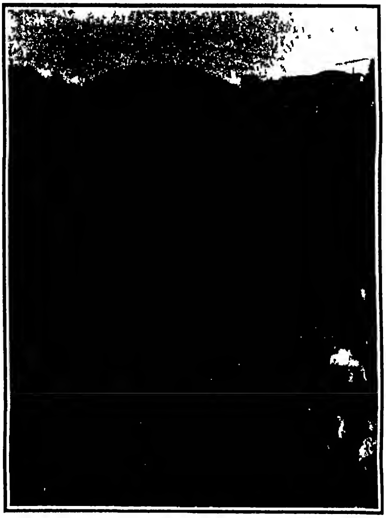
The new railroad passes through the wildest and most picturesque spots of the Jura Mountains and in its location follows the course of the Valserine stream, a tributary to the Rhône. This rivulet is crossed twice, first by means of the Bellegarde viaduct, comprising seven spans each of 60 feet in the clear by 150 feet in height, and secondly by a handsome masonry bridge, the Moulin des Pierres or Montangas, which has a main span of 262 feet 9½ inches.

At the latter crossing the river flows through a deep rock gorge, the precipitous banks of which are over 170 feet in height. The rock was found to be of such excellent bearing quality that the engineer in chief decided to use the cliffs as the abutments of a large single arch. The latter, in springing from the sides, has a radius of 164 feet ⅛ inch for the arc at the intrados and of 177½ feet at the extrados. The thickness of the masonry at the keystone is 4 feet 11 inches and at the springing 8 feet 2¼ inches, while the width is 17 feet 10½ inches, increased at the coping to 20 feet 8 inches between parapets, which is sufficient to provide width for two foot pavements, a railroad track of meter gage, and a roadway paralleling the railroad track.

The eleven small arches which surmount the great span on either side have semicircular openings of 17 feet 4½ inches clear. They are carried on piers having a thickness at the top of 3 feet 5⅝ inches, and the sides parallel with the axis of the stream have a batter of 1 in 10 from the point at which they rise from the main arch.

Owing to the depth of the ravine, the erection of such a large single-span bridge called for some extensive framework. As the keystone of the main span is approximately 217 feet above the level of the water, it was necessary to erect wooden falsework from the stream to the level of the abutments to carry the centering, and this temporary work comprises three substantial towers built of wood and strongly braced together. The towers were each some 133 feet in height and were erected on masonry piers 13 feet in height built on piles driven in the bed of the stream.

In erecting the towers it was imperative that ample provision should be made for wind pressure, as



Timber falsework ready for the laying of the masonry.

the storms which drive through this ravine are often of extreme severity. This was accomplished by tying the towers to each other and to the embankment rock and the pier bases by steel cables so arranged as to provide a system of bracing which served to hold the whole of the falsework perfectly rigid. The intricate character of the timber centering is plainly visible in the accompanying illustrations, and it may be mentioned that in this part of the work 21,188 cubic feet of wood and 10 tons of iron and steel were used.

In placing the masonry in position care had to be observed to guard against any sinking of the timbering under the superimposed weight, and in order to lessen the extent of any deformation from this cause the engineers caused the stonework to be laid in eight sections independent of one another, which were finally connected together. An aerial cableway was erected across the gorge, by means of which the timber piers, centering and arch were erected, the whole of the material being conveyed to its site and set in position by this means.

The bridge was commenced in August, 1908. By January 17th of the following year the whole of the timber falsework had been set up, and the erection of the masonry was completed by August 31st last. When the masonry work was finished the timbering was dismantled. The removal of the centering was accomplished by emptying the boxes filled with sand on which the various parts of the falsework frame rested, which dropped the whole of the timbering sufficiently to enable it to be handled. The falsework was demolished without any movement being noticed in the masonry by November 7th last. When completed the bridge will excel in span any similar work existing in France, while its height over the valley, which is equal to that of the towers of Notre Dame in Paris, is greater than that of any other large single-span masonry bridge elsewhere in the world. Its total cost will approximate $72,000.

---

According to the Electric Railway Journal, experiments with a method of increasing traction by magnetic wheels have been conducted for some time by Mr. D. Heinze of Lowell, Mass. The wheel contains four magnet coils, outside of which are four segments comprising part of the tread of the wheel, and a ring of 1 per cent manganese steel is clamped between them and the wheel proper to send the magnetic circuit into the rail. The energizing of the magnets is so timed that each succeeding section of the wheel is attracted to the rail just in advance of making contact with it, so that the device, besides giving increased adhesion, also assists acceleration. The current is cut off from each given segment as soon as it is no longer in contact with the rail. Tests have been made on a truck equipped with two 3 horse-power 500-volt standard railway motors and weighing 11,000 pounds. With the traction due to weight alone the motors developed a drawbar pull of 2,00 pounds. With the wheels magnetized the tractive effort was increased to 4,500 pounds, or more than 00 per cent. The inventor does not claim to increase the traction by such a liberal percentage on an ordinary car, but states that a car equipped with his device should be able to mount grades that are otherwise impossible without a rack

The masonry of the main arch was laid in eight independent courses.

The arch has a clear span of 262 feet 9½ inches; it stands 217 feet clear of the river.

BUILDING THE MONTANGAS MASONRY ARCH BRIDGE.

## OUR MARVELOUS AUTOMOBILE INDUSTRY

If ever an industry has grown by leaps and bounds, surely it is that of making motor cars. Even the bicycle in its palmiest days did not produce machines whose total value for ten years could equal the truly enormous sum of money represented by the automobile products made in the United States between 1895 and 1910. Mere figures tell but little. For that reason we have presented on the front page of this issue a graphic illustration, in which the wonderful strides made in the manufacture of motor cars are tellingly depicted. These strides are all the more remarkable when it is considered that the industry had to weather the severe financial depression of 1908, a period which was one of the most critical in the recent financial history of this country.

Considered merely from the standpoint of money, the automobile industry in this country presents a most wonderful spectacle. The total estimated value of automobiles to be manufactured in 1910 is $237,000,000. When the industry was born in this country, which was in 1895, the estimated value of the machines turned out was only $157,000. In the brief space of twelve years, therefore, we have created an industry whose annual product is valued at millions. The intermediate stages between 1895 and 1910 show a growth which is stupendous. The stage from 1895 to 1899 marked an increase in the total value of nearly a million dollars, the actual value of automobiles manufactured in 1899 being $1,290,000. Still more remarkable is the development from 1899 to 1903, for the valuation of the automobile product in this country increased nearly sixteen fold in that time, the actual value of automobiles produced in 1903 being $16,000,000. Remarkable as that increase undoubtedly was, it was almost equaled by the interval from 1903 to 1907, for in 1907, $105,000,000 worth of automobile machinery was manufactured. From the year 1907 to 1910 a 100 per cent increase is to be expected. In other words, in these three years the mere increase in value of the automobile industry will be greater than the total value of the industry in the year 1907.

An industry which has grown with such startling rapidity and which is valued at so princely a sum, naturally gives employment to an army of mechanics, all of them skilled men handsomely paid. Thus we find that the mere wages paid for mechanics in 1910 will amount to about $100,000,000. The chauffeurs who drive the many cars which were in use in 1910 will earn $25,000,000 at the very least in 1910.

The number of automobiles produced is nothing short of staggering. If all the cars of 1910 were placed end to end, they would reach from New York to Pittsburg, a distance of 438.76 miles. This output of 200,000 is three times greater than that of 1907, considered from this linear standpoint, for the automobiles of 1907, had they been placed end to end, would have extended from New York to Harrisburg, a distance of 191.95 miles. Compared with this, the 13,333 automobiles manufactured in 1903 seem exceedingly small, although as a matter of fact the machines for that year, had they been placed end to end, would have extended from New York to New Brunswick, N. J., a distance of 29.25 miles. Even this, small as it seems in comparison with the gigantic production of 1910, is huge when we consider that between 1895 and 1899 the 670 automobiles produced in this country would have extended only from New York to Jersey City, a distance of 1.46 miles.

Had all the automobiles made in 1910 been converted into a single huge machine, the result would be, as our front page illustration shows, a car which would be longer than the steamship "St. Paul," measuring 554 feet from stem to stern. Even the output of 1899 had it been thus converted into a single machine, would have been longer than the "St. Paul." The machines of 1903 similarly considered would have been three-quarters as long. The output of 1895-1899 is, of course, vanishingly small in comparison with this gigantic trans-Atlantic steamer.

Naturally an industry of such Titanic proportions must be capitalized at millions. On the whole, it is safe to say that the actual capitalization of the automobile manufacturers is about $250,000,000. The output for 1910 alone will surely exceed 200,000 cars. Even now there are over 150,000 automobiles in use throughout the country. The actual number of employés in the industry is 125,000 in motor-car factories, with employés in parts factories reaching not less than 40,000, a total of 165,000.

Hand in hand with this increase in money value, we find improvements in manufacturing processes. Five years ago, where a man would have paid from $2,000 to $2,500 for a touring car, or $650 to $1,200 for a runabout, he scarcely expected to get much in the way of durability, or if he did, in the exuberance of unsophisticated anticipation, he was almost sure to be disappointed before he had used the car many days. When we recorded the automobile runs of those days in these columns, we usually had to recite a series of troubles of various sorts, chiefly with tires, carbureters, ignition devices, as well as breakages and imperfect functioning of valve mechanisms, shafts, gears, chains, steering knuckles, driving axles, and other vital parts. Contrasting this condition with the results of the Glidden Tour of 1909, we find that thirty cars took part in that run and finished an arduous trip of 2,640 miles in 15 days, at an average speed of twenty miles an hour during the daylight running periods, without making a single involuntary stop. That tells the tale of the wonderful technical improvements which have been effected in the brief space of a few years. It is rarely indeed that repairs are made during runs nowadays. Occasionally a brake, a carbureter, an ignition system, may have to be adjusted, or a tire may blow out, but the cars operate smoothly and trustworthily.

The introduction of special grades of steel, aluminium, vanadium, and babbitt, all of them endowed with definite physical properties peculiarly suited to the requirements of automobile manufacture, have wonderfully improved the quality of the motor car. Nickel steel and chrome-nickel steel are now used in crank shafts, transmission shafts, driving axles, driving and differential steering gears, steering knuckles, and similar parts, manganese-bronze, phosphor-bronze, and various aluminium alloys find their places in crank-cases, gear boxes, steering gear housings, and parts demanding great stiffness combined with light weight.

The automobile industry is very largely responsible for the discovery of the physical properties of chrome-nickel steel and vanadium-chrome steel under different modes of heat treatment and for the introduction of special tool steels required to work them, and has thus indirectly benefited the metallurgical industry of this country. As a result of the employment of these new steels in the sliding gear sets, by way of illustration, it is now possible to transmit the 40 and 60 horse-power of the modern touring car with smaller and lighter gear sets than were used in cars of 12, 15 and 20 horse-power five years ago, and that with much greater certainty against breakage and the practical elimination of the mangling of the ends of the teeth by meshing and of wear due to contact under load. All this improvement in quality, plus infinitely more grace in general lines and in comfort to the passengers, is offered to the buyer almost at no advance in cost over the ungainly, uncomfortable, and poorly-equipped cars of six and seven years ago. It is safe to say that a great proportion of the automobiles manufactured in 1910 will be low priced cars. The car that could be bought a few years ago by the man of moderate income required close attention. Automobiling at that time was unquestionably a diversion for the rich. Nowadays a man of moderate means can purchase and use a car at an expense that is well within the bounds of reason.

In the early days of the automobile industry, the manufacturer was under the necessity of making all his parts, to-day the factories actually making even 75 per cent of the parts that they use are in small proportion to the number of producers. It is to these changes that the excellence of the medium priced automobile is largely due. There was a time when an assembled car was undoubtedly open to suspicion, for however desirous a maker of its parts might be to do good work, he had neither the knowledge nor the facilities that would make it possible. These same companies now possess enormous plants. Their designers and equipment are the best obtainable and their products embody the latest and best in practice, workmanship, and material. Assemblers now have at their command parts of a high degree of excellence, and can buy them at prices far below those charged for the weak and faulty product of former years.

When a manufacturer turns out twenty thousand cars a year it is not only justifiable but necessary for him to invest very considerable sums in special machinery of all kinds that for a smaller output would be inadvisable. One manufacturer has spent $40,000 for dies to produce a rear axle housing, on a production of one thousand cars, the charge against each for this would be $40. With an output of twenty thousand cars, however, the charge of $2 against each is little enough for the purchaser to pay for so excellent a feature.

A recent development that illustrates the endeavor to reduce manufacturing costs is the establishment by some of the leading producers of assembling shops at the large centers. To these are shipped parts in sufficient quantity to build the cars required for that locality, and as there is no equipment of machine tools, the expense is slight. The freight rate on unassembled parts is much lower than on complete cars, and the saving effected in time and convenience as well as in money makes the system a satisfactory one.

Vast as the automobile industry is, huge as is the value of its output, it must not be supposed that the profits are illegitimate. It is safe to say that the present-day manufacturer of medium-priced cars makes no more than a legitimate profit. One of the largest producers stated recently that his profit on a $1,000 car is less than $100, surely not excessive when one considers his enormous investment in material and parts, his really vast equipment of machine tools, and his labor expense.

It has been said that any average engineer can design a car to sell at $4,000, but that the greatest skill is necessary when the selling price is to be less than $1,000. Perhaps that may account for some of the exceedingly clever designing in the low-priced cars.

The scene of the industry has shifted in the years from 1895 to 1910. Much of the early experimenting in motor cars and early manufacturing was done in Buffalo, Tarrytown, Marion, N. J., Bridgeport and Hartford, Conn., Philadelphia, Pa., and other Eastern States. At present Michigan leads all the States in motor-car manufacturing, for that State last year made 112,000 of the total production of cars for 1909. Four other States adjoining it will produce 75,075 machines at least. The Middle West may therefore be said to be the real home of the automobile industry at the present time. It controls not only the car-making industry, but the making of tires, parts, and accessories as well, a condition which is primarily due to the industrial enterprise of the smaller communities of the Middle West, who have given land and in every way furthered the making of automobiles. It must also be considered that the makers of automatic machinery are very largely situated in the West, for which reason the better class of skilled labor is there to be found. Lastly, the shifting of the industry from the East to the Middle West has been caused in part at least by the fact that the raw material is there put through its first and second processes, as in the case of rubber, steel, leather, wood, brass, and the like.

That the Middle West is undoubtedly benefited by the influx of automobile manufacturers can be shown by the wonderful increase in the population of some of the smaller towns. The influx of 2,000 to 5,000 families has doubled and trebled the populations of such cities as Flint, Mich., and Newcastle, Ind., and greatly enhanced the value of real estate. Towns which were practically unheard of before the automobile entered into our daily life are now thriving centers of industry. Communities with a population of only five or six thousand have their names brought home through the magazine advertising pages to millions and millions of readers, simply because they are the sites of large automobile plants.

### Cost of Various Methods of Illumination.

The Frankfurter Zeitung publishes the following remarkably complete table of the cost of various methods of illumination.

| | Cost of 100 normal candle hours. Cents |
|---|---|
| Washington light | 0.238 |
| Flaming electric arc | 0.381 |
| Mercury vapor lamp | 0.595 |
| Incandescent gas light | 0.595 |
| Incandescent petroleum light | 0.714 |
| Direct current electric arc | 0.942 |
| Osram, zircon and tungsten lamp | 1.190 |
| Kerosene burner | 1.666 |
| Osmium lamp | 1.785 |
| Tantalum lamp | 1.904 |
| Incandescent alcohol lamp | 1.904 |
| Alternating current electric arc | 1.904 |
| Nernst lamp | 2.023 |
| Small arc lamps | 2.142 |
| Acetylene | 2.856 |
| Carbon filament | 3.808 |
| Argand gas burner | 3.808 |
| Fishtail gas burner | 5.950 |
| Stearin candle | 26.180 |

The Washington lamp is an incandescent lamp which burns petroleum under pressure.

In compiling this table the following average prices for fuels and electrical energy have been employed:

| | |
|---|---|
| Kerosene | 2.38 cents per pound |
| Alcohol | 4.33 cents per pound |
| Stearin candles | 16.23 cents per pound |
| Gas | 107.87 cents per thousand cubic feet |
| Acetylene | 809.07 cents per thousand cubic feet |
| Electric energy | 11.90 cents per kilowatt hour. |

According to plans formulated by Rear-Admiral Cowles, chief of the Bureau of Equipment of the United States navy, and submitted by him to Congress, wireless apparatus of the latest type is to be supplied to all the new vessels of the navy, including destroyers and all auxiliaries, as this latter class of vessel has proved very valuable in establishing wireless chains across long stretches of ocean without the necessity of disrupting the fighting fleet. Another shore station is contemplated at Dutch Harbor, Alaska, to provide wireless communication to Bering Sea, connecting with the Cape Nome station, permitting vessels from Nome to lower California to keep in touch with the world. After the contemplated high-powered station in Washington has been completed it is believed similar stations will be found necessary in the following places: The west coast of the United States, the Panama Canal Zone, Hawaii, and the Philippines. With stations at these places vessels will be within call while in practically all waters where naval operations of interest to the United States might be expected. Each station will cost $100,000.

### PFITZNER'S MONOPLANE.

To the Editor of the SCIENTIFIC AMERICAN

I have just read with much interest an article in your issue of February 12th under the caption "A Novel American Aeroplane."

The monoplane has always appealed to me as being more consistent with the laws of nature, and therefore more susceptible of continued improvement and eventual perfection, than the biplane. The double or triple planes strike me as being contrary to the examples set us by Nature, the extra planes being a superfluity of which Dame Nature is rarely, if ever, guilty It would be an incongruity for a bird to be supplied with more than one pair of wings, unless the duplex or triplex wings were accompanied by a Siamese-twin or triplicate body As long as there is but one body and one source of motive and controlling power, a single pair of supporting planes would appear to be all that is necessary if the planes are sufficiently extended to support the body at the speed normal to the bird Additional planes do not sufficiently compensate by their increased buoyancy for the increased weight, unwieldiness, and instability I therefore pin my faith to the monoplane as likely to afford an additional illustration of the truth of the Darwinian theory of "the survival of the fittest"

Mr Pfitzner's design, according to my ideas, comes nearer to the ideal heavier-than-air flying machine than anything that has heretofore been brought to my attention. I will be greatly mistaken, and disappointed as well, if we do not hear from his machine ere long as successfully rivaling even the best of the biplanes.

But even Mr Pfitzner's novel design is susceptible of improvement I cannot help wondering why neither he, nor any other aviator as far as I have been able to observe, has adopted what I consider to be a very essential element of stability invariably to be found in the make-up of the denizens of the air I mean the invariable disposition of the weight of the body to the supporting planes. Mr Pfitzner seems to have entirely ignored this principle, like all other aviators, by placing his engine and driver's seat above or on a level with the supporting planes.

Nature, on the contrary suspends nearly the entire weight of the bird below the level of the wings or planes, evidently for the express purpose of securing stability During flight, or particularly while soaring, the extended wings of the buzzard (to adopt a familiar example) are held in a plane slightly above the point of their juncture with the body, while at the same time the head is lowered and extended forward, so as to bring it down to or beneath the plane of the wings While the bird is sailing in a calm atmosphere, the legs and feet are drawn up toward the body, but let a sudden gust of wind strike under one wing and tend to displace the center of gravity, the legs are at once extended in order to lower the center of gravity, and equilibrium is at once restored This seems to me to be a wise provision of Nature worthy of imitation as far as is practicable by the aviator

With the engine, and naphtha and water tanks, as well as the seat of the aviator, rigidly suspended as far as conveniently possible below the planes, the weight acts like a pendulum, the plumb-bob of the mason, or the ballast of a ship, its constant tendency being to restore the equilibrium of the planes the moment the disturbing force is removed And in making a change of direction, if the radius of the curve is abrupt, the tendency of the outer plane to rise on account of its increased speed as compared to the retarded speed of the inner plane will be measurably counteracted With the weights so disposed, the extended planes will act like a parachute, and in case of the sudden breakdown of the engine or propeller would, in conjunction with the usual downward glide of the machine, enable the aviator to alight in an open space "right side up," without damage to either himself or his aeroplane

Were Mr Pfitzner to raise his planes to the tops of the vertical posts, and lower the engine, tanks, and seat to a level with the axles of the carriage, he would find that much less skill would be required to preserve the equilibrium of the machine Possibly the propeller shaft should remain on a level with the planes, but if lowered just far enough to enable the blades to clear the ground, I apprehend he would be able to make a quicker start The tendency to drive the plane upward would assist it in leaving the ground, and, once afloat, that tendency, if persisted in, could readily be counteracted by the proper use of the forward horizontal rudder, without perceptibly impeding the speed of the flyer

I would suggest another scheme for the rudders. Let them be connected together, so they would move in unison When the horizontal rudder is elevated or depressed in order to rise or descend, it would make no material difference if the perpendicular rudder did also rise and fall in a perpendicular plane It would produce no change in the direction In like manner, if the perpendicular rudder should be turned to the right or left in order to alter the course, it would have no influence on the elevation of the machine.

I possess but a superficial knowledge of aviation, and I have no means for investigation or experiment, but I have been intensely interested in the science ever since the Wrights' experiments were first made public The above thoughts came to me as I read and pondered the description of Mr Pfitzner's novel device I make bold to offer them to you for publication if you deem them worthy of being embalmed in print.

Norfolk, Va C E McClure

### THAT NUMBER PUZZLE.

To the Editor of the SCIENTIFIC AMERICAN

If your correspondent in the issue of January 22nd will study the following figures, he will plainly see that it is *not* impossible to get 35 sets of 3 out of 1—15, so that no two numbers will be in the same set more than once

| | | | | |
|---|---|---|---|---|
| 1— 2— 3 | 2— 4—10 | 3— 6—11 | 4— 9—12 | 6— 9—13 |
| 1— 4— 6 | 2— 5—11 | 2— 7—12 | 4—13—14 | 6—10—14 |
| 1— 5— 8 | 2— 6—12 | 3— 8—13 | 5— 6— 7 | 7— 8— 9 |
| 1— 7—10 | 2— 7—13 | 3— 9—14 | 5— 9—10 | 7—11—14 |
| 1—12—14 | 2— 9—15 | 4— 7—15 | 5—14—15 | 10—11—13 |
| 1— 9—11 | 2— 8—14 | 3—10—15 | 6—12—13 | 8—10—12 |
| 1—13—15 | 3— 4— 5 | 4— 8—11 | 6— 8—15 | 11—12—15 |
| 1— 2— 3 | 2— 4— 6 | 3— 5— 6 | 4—10—14 | 6— 9—12 |
| 1— 4— 5 | 2— 5— 7 | 3— 8—11 | 4—11—15 | 6—10—15 |
| 1— 6— 7 | 2— 8—10 | 3— 9—10 | 5— 8—14 | 6—11—14 |
| 1— 8— 9 | 2— 9—11 | 3—12—15 | 5— 9—15 | 7— 8—15 |
| 1—10—11 | 2—12—14 | 3—13—14 | 5—10—12 | 7— 9—14 |
| 1—12—13 | 2—13—15 | 4— 8—12 | 5—11—13 | 7—10—13 |
| 1—14—15 | 3— 4— 7 | 4— 9—13 | 6— 8—12 | 7—11—12 |

If he will carefully inspect the 30 sets of numbers presented by him in the same issue, he will discover that the numbers 4 and 6 are twice paired, leaving only 29 sets without duplicates

Milwaukee, Wis Lewis Sherman

### REBUILDING THE "IDAHO" AND "MISSISSIPPI."

To the Editor of the SCIENTIFIC AMERICAN

As one of your readers, I have been following with interest the proposals put forward by various gentlemen regarding the reconstructing and rearming of the different types of pre-dreadnought battleships in our navy

In the March 5th number of your paper you published a letter from Mr W W Bass concerning a proposed rebuilding of the battleships "Idaho" and "Mississippi" so as to make them nearly equal to the Louisiana" class. One of the objections put forward was the impossibility of establishing a 10 inch gun in a turret built for two 8-inch Why not avoid this difficulty by leaving the eight 8 inch guns already mounted where they are and then to increase as much as possible the 7-inch battery below? This would make these ships even more similar to the "Louisiana"

I do not believe that the cutting in two of a battleship would entail very great difficulties as a few years ago a White Star liner was cut in two and a new bow built on the original having been destroyed by an accident. A torpedo-boat destroyer of the British navy also was rebuilt in this manner

But if it was deemed too expensive to build this section as proposed, would it not be feasible to sacrifice a few 7 inch guns and re-engine the ships with turbines of greater power thus attaining the extra knot and a half necessary to bring them up to the "Louisiana's" speed standard without the cost, time, and labor of totally rebuilding them?

Leonard Opdycke

New York, March 21, 1910

[The "Idaho" and "Mississippi" are so much shorter than the "Connecticut" that there would be no room for the mounting of additional 7-inch guns It would be useless to install turbines in these ships without increasing their length and the cost of both changes would not be warranted by the advantages of additional 7 inch guns and the greater speed secured thereby The deficiencies in these ships are due to the action of Congress in limiting the displacement to 13,000 tons —ED.]

### Death of Alexander Agassiz.

Prof Alexander Agassiz died on the steamer "Adriatic" on March 29th, while on his way to New York Hardly less famous as a scientist than his father, he was noted not only as a biologist but as a mining engineer financier, teacher and man of the world In his life he combined the activities of president of the Calumet and Hecla Mining Company and director of the Museum of Comparative Zoology at Harvard, founded by his father Prof Agassiz was born in Neuchatel in 1835 and did not come to this country until he was fifteen His early education was received in Europe, although he was graduated from Harvard with the class of 1855 He started out in life as a civil engineer, and did much valuable work as assistant on the Atlantic Geodetic Coast Survey His work in that field naturally drew his attention to the natural sciences. He began to collect fishes for his father, and thus was induced to follow in his father's footsteps. After that his activities were almost equally divided between zoology and mining

A study of the copper mines of Peru and Chili led him to a survey of Lake Titicaca, and also to collect Peruvian relics, which are now lodged in the Peabody Museum at Harvard Five years of his life, from 1876 to 1881 he spent in deep-sea dredging His biological survey of the waters of the Gulf of Mexico and the Caribbean Sea is still regarded as classic

His exploitation of the Calumet and Hecla mines to his profit secured the means to gratify his father's ambition, the erection of the great Harvard Museum of Comparative Zoology

He made by his persistence and ability in argument the development of the Lake Superior copper territory on Keweenaw Point (and now later traced to the mainland) a certainty

### Death of Hermann Moedebeck.

Oberstleutnant z D Hermann Moedebeck died recently With him there has passed away one of the most ardent advocates of aero-navigation Thanks to his efforts the Deutsche Verein fuer Luftschiffahrt included in its programme meteorological measurements. As a young lieutenant, Moedebeck became a member of the Deutsche Verein zur Förderung der Luftschiffahrt. As a captain he founded in Strasburg the Oberrheinische Verein fuer Luftschiffahrt, and published its official organ, Illustrirte Aeronautische Mitteilungen, now the official organ of all the German aeronautic societies In 1907 Moedebeck was promoted to Oberstleutnant A year later he retired from active army service in order to devote his entire time to aeronautics He was a member of the International Commission for Scientific Aeronautics and a charter member of the International Commission of Aeronautic Maps It was only recently that he founded an aero Luftflottenverein fuer Berlin und Brandenburg

### Death of Galen Clark.

Galen Clark, who died in Oakland Cal, on March 24th, had been known for the last half century to almost every tourist who has visited the Yosemite Valley While on a hunting trip in 1857, he discovered the great redwood grove at Mariposa Soon after that Clark devoted much of his time to exploring the upper heights of the Sierra Nevada Mountains, and made known to the world much of the beauties and wonders of the big tree groves and of Yosemite

### The Current Supplement.

In the current SUPPLEMENT, No 1788, Mr P M'N Bennie reviews the recent work which has been done in the electrical reduction of iron and steel There is much confusion with regard to dyestuffs and the colors which they impart to the textile fabric, and this confusion Prof Otto N Witt seeks to remove Some very interesting novelties in toys are described and illustrated Lieut. John C Soley exhaustively discusses the oil fields of the Gulf of Mexico In an article on the South Pole will be found mentioned the various schemes which have recently been put forth to reach the South Pole Prof George E Hale's admirable consideration of solar vortices and magnetic fields, in which he reviews his recent study of the sun is concluded Halley's comet is now visible to the naked eye just before dawn in the eastern sky, for which reason Mr George F Chambers's most thorough article on this interesting wanderer is published with peculiar timeliness One of the most important articles in the SUPPLEMENT is Mr Aston's account of the recent Olympia aero exhibition by far the biggest of its kind which has ever been held in Europe

According to the Engineering Record improved boiler performance has been attained at the Anderson station of the Indiana Union Traction Company by preventing the leakage of air from the ashpits around the ends of the chain grates into the flues. This is accomplished by first fixing a 4 inch extra-heavy pipe across the furnace 8 inches from the rear of the grate, with its lower surface 3½ inches above the top of the grate There is a span of about 10 inches between the center of the pipe and the rear fire box wall, which is covered with a course of fire-brick This shelf prevents the passage of air, while the pipe holds back unconsumed coal until it has been burned into ash, which the grate can carry back under the pipe in the desired manner Inside the 4 inch pipe is one of 1 inch diameter running from one end nearly to the other Cold water is admitted through the small pipe and flows back through the large one, the rate of flow being adjusted so that its final temperature is just under the boiling point The hot water is discharged in a way that permits its condition to be inspected, into a header delivering it to the hot well.

# OUR SEACOAST DEFENSES

BY CAPT. H. E. CLOKE, U. S. ARMY

When the Constitution of the United States was framed creating a republican form of government provisions were made for the creation of military and naval forces and for the existence of State troops for the purpose of repelling of invasion

Owing to the fact that access to our coast fortifications has in years past been prohibited to the citizens of this country it is not surprising how few men understand the method of firing a high powered gun or a modern mortar For this reason the following de-

I t as l en fo   l   pra tic  that th s type f disap  ari g g   is a  rapid fire gun   It can act ally be fired more rapidly ... l   l   l  ria  t  try   l  ls g   l as se  ral 100 p r   nt of hits at 6 000 yards range several times

Positions of detachment at command "Load" for 6-inch disappearing rifle.

The range finder is the eye of the system while the telephone and telautograph are its nerves The hitting power of a battery absolutely depends upon its range finder

A range-finding room. (B[1] station)

No better service could be rendered to the country and there is no service that should appeal more to the patriotism of our State troops than this and particularly the troops of those States which border the coast to be defended Our organized State militia and the various labor organizations should be attracted to the subject of coast defense for the reason that men in such organizations are unable to leave their families and business interests and enlist for general service in time of war If they were organized as a defensive force for the protection of their homes against invasion the defensive forces of the State and country would be increased by a body of men of a high order of patriotism and intelligence

When one contemplates the cost our coast defenses certainly do appear to be an expensive investment For example a 12 inch gun complete costs about $14? 000 and as there are about one hundred of these guns mounted in our coast forts the cost of the 12 inch guns alone amounts to $1? 000 000 On the other hand we must remember that this sum does not equal the cost of two Dreadnoughts It costs about $60) every time one of these guns is fired with an armor piercing explosive shell but one of these shells if directed at the proper point on a modern battleship will inflict hundreds of thousands of dollars worth of damage Although one submarine mine charged with a hundred pounds of nitro glycerine costs about $?00 it may if exploded underneath a battleship send many millions of dollars to the bottom of the sea On the other hand the life of the 12 inch guns without re rifling is only about 240 rounds that is to say firing one shot every thirty seconds (the time of fire of a 12 inch rifle) the gun becomes useless after a two hour engagement

scription illustrated by the different drawings is given

Let us consider the enemy's fleet to have been sighted on the horizon and headed under full steam in column formation for the entrance of a harbor The attack is being made during a late hour of the night On the discovery of the leading ship by the powerful

In the telescope of this instrument are vertical and horizontal cross hairs As the eyepiece of the telescope is elevated or depressed the waterline of a ship ... the base plate ... graduated in yards of range The ... of intersection of the horizontal cross hair with the waterline of a ship therefore determines the range automatically This instrument is the invention of Major Lewis of the coast artillery corps

Lewis position finder.

searchlights of the defense the battle commander directs the sounding of call to arms Within ten seconds every soldier is at his station or post for duty for in case of imminent attack the men sleep at the guns. The battle commander then notifies the fire commanders by telephone of the approach of the fleet The fleet would probably be picked up at ten or twelve thousand yards. At this range all the heavy batteries including mortars are directed on the leading ship The probability of hitting her by this means would of course be greater than if the fire were dispersed All guns attack the side armor and turrets of a battleship while the mortars attack the decks The searchlights of the different fire commands are now concentrated on the leading ship while the battle command lights are searching for undiscovered ships

In order to fire a modern 12 inch gun the following data must be accurately determined

The elevation to be given to the gun (which is a direct function of the range) and the amount of deflection to be set on the sight If the gun were merely set for the range from the gun to the target the probability of hitting would be very small The errors that enter into the range function are as follows 1 The accelerating or retarding component of the wind 2 The variation of the height of the gun above water level due to the height of tide 3 The variation of the resistance offered by the air due to its density 4 The variation of the initial velocity of the powder due to temperature or other causes 5 The change of the range due to the speed of the target These corrections must be applied to the range with lightning rapidity it is accomplished by the use of certain mechanical contrivances which are located in the various fire control stations of the fortress

The deflection correction to be set on the sight is the algebraic sum of the component of the wind the drift and the speed of the target and it is determined by means of mechanical devices located in the plotting rooms The following then would be the method of determining the range and deflection to be sent to the guns by telautograph or telephone At the simultaneous ringing of the bell in the primary

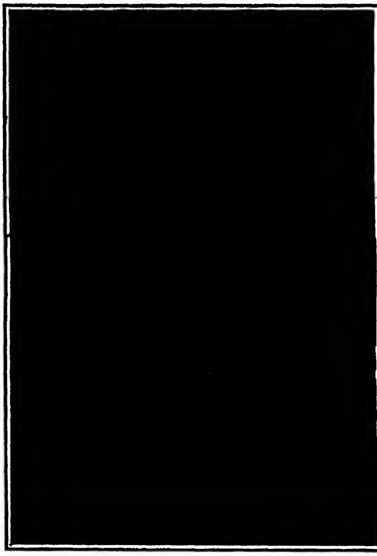
It is in this room that specially trained men determine from data received from the range finders the course of a target and its predicted position This predicted range is sent to the guns of a battery and by the ringing of a bell the predicted time is announced and the gunner fires by ... device

A plotting device.

These weapons attack the most vulnerable part of a ship—the decks. Each one is loaded with a 1,000-pound shell which is filled with about 100 pounds of high explosive which detonates on striking Sixteen of these mortars are fired at once. Their extreme range is 12,000 yards. At long ranges they are more accurate than guns.

Positions of detachment at command "Posts" for 12-inch mortars.

and secondary stations, the observers at the instruments read the azimuth angles at the base ends. These angles are immediately plotted on the plotting board, and the position of the target with reference to the center of the gun is determined. At the expiration of 15 seconds, the bell again rings, and the target is again plotted. The course of the ship is then accurately determined and, by means of a mechanical device on the gun arm, the amount the target has changed in azimuth, due to its speed, is determined. The last range read is now set on a device called the range board. This device is practically a graphic adding and subtracting machine. The corrections above referred to for atmosphere, wind, tide, etc., are here applied, and the resultant correction (a reference number) is set off on the gun arm of the plotting board, and corrected ranges are now sent to the gun by telephone or telautograph. This range is called the corrected predicted range to the target. It is predicted for an interval of 15 or 30 seconds ahead. It is now plugged in on the time range relation board, which is in full view of the range keeper at the gun. The range keeper keeps the range disk continually set at the corrected range (as observed on the time range relation board) such that the gun can be fired at any time. The deflection correction is obtained by the use of a device called the deflection board. This, as in the case of the range board, is an adding and subtracting machine which determines the number of degrees and minutes of deflection to be set on the sight due to wind, drift, and speed of target. The drift is determined by ballistic calculations, and the curve is constructed on a metal leaf on the board. The velocity of the wind is determined at the meteorological station by means of an anemometer, and is received at the plotting room by means of an electrical device called the aeroscope shown in



Groups of these deadly weapons of destruction are planted across channels to keep the enemy out. They are harmless to friendly ships and are entirely controlled from a casemate on the shore. The new system of submarine mining of our army is a great triumph of electrical engineering. The principles of its operation are kept secret. The high explosive is contained in the floating metal sphere.

A complete submarine mine

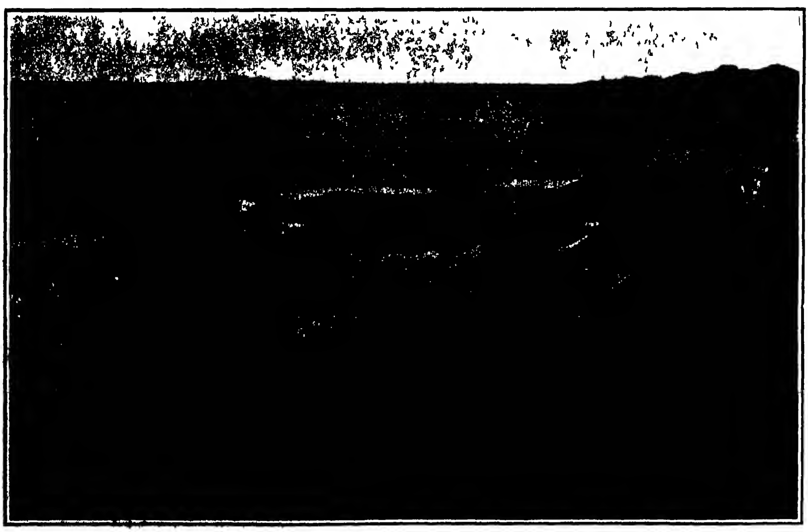
(Redrawn from Coke's "The Gunner's Examiner," published by John Wiley & Sons.)

the drawing. The azimuth of the wind is also sent by the same means. The components in the direction of range and deflection are determined by means of a device called the wind component indicator, shown in the picture. The atmosphere correction is determined in the meteorological station and is sent in over the aeroscope. The height of tide is determined by a tide gage. The velocity correction is determined by a device called the powder chart.

Owing to the fact that these corrections may be either additive or subtractive, and that the use therefore of a negative sign tends to confuse the gunners in the plotting room, these corrections to be applied to the range are not sent in according to their actual values, but by means of reference numbers. The zero of the sight, for example, is the number 3. The gunner at the sight therefore would receive a deflection like this: 4.25. He simply sets his sight to read this deflection, and the gun will then be correctly aimed. It is to be understood that all these fire control instruments and stations are located at obscure places in the fort reservation, and are amply protected by parapets of earth and concrete. They are connected with each other by either telephone, telautograph, or speaking tube, all of which are laid underground deep enough to insure ample protection from ordinary gun fire.

The fire control system of our coast artillery is also very flexible. If the horizontal base system fails, each observing instrument at the primary and secondary stations can be used as a vertical base range finder, and the system is so arranged that in case all the range finders except that of the fire commander are put out of action, his station can supply all the guns with the necessary data for firing them. Furthermore, if all the stations including the fire commander's should be

(Continued on page 316.)



This diagram shows in a general way the arrangement of an up-to-date battery. The position of the enemy is found by observing the angles the ship makes at two observing stations B' and B'' situated at the end of a common base line of known length. These angles are telephoned to the plotting room where the position of the ship is found. From the plotting room the proper elevation, etc., is telephoned to the gun.

# OUR CIVIL DAY

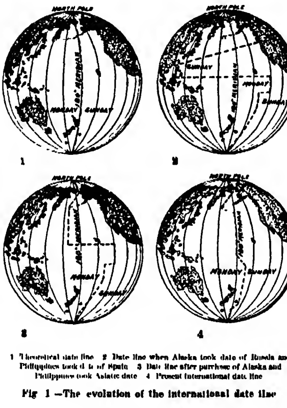
## ITS ARRIVAL ON AND PROGRESS AROUND THE EARTH

BY DANIEL ARTHUR

A few generations before our era the "whole known world" was only some 25 million square miles in extent instead of nearly 200 millions as we now know. That great observer and geographer Eratosthenes made a noble attempt about 225 B. C. to draw a map of the "World." He even used lines which looked very like parallels of latitude and circles of longitude. These lines were largely based on the speed records of travelers and hence were not very accurate. There were no such refinements on his maps as international date lines or time zones. His general outline of the "whole world" was about 90 deg. wide east and west by 60 deg. long north and south. It was all above our equator, and extended only about a quarter of the way around the earth. The mouth of the Ganges was farthest east and what is now Ireland was farthest west. The Caspian Sea was thought to be an arm of the Northern Ocean, while the lower end of the Red Sea was about the southern limit. Knowledge of the rest of the world grew very slowly then, as was shown by the fact that the great Strabo drew a map of the "World" two hundred years later (about 25 B. C.) and made no material extension of its lines. He pushed Great Britain and Ireland farther west and made some radical changes on the northern edge of the Mediterranean, but otherwise those two maps of two hundred years apart are practically the same. There is very little doubt, however, that Strabo thought the world to be round, before he died. Hence the necessity for a date line was felt even at this early date.

While the spherical earth idea was passing through its hundreds of years of resistance some radical observers started it spinning on its axis so to speak. They were bold men, but they proved their case. This brought the date line as a necessity closer to us. It would almost seem that with a "flat disk world" converted into a stationary globe, and later into a rotating globe the date line idea should have suggested itself at once. Not so, however, for it appears that when Magellan crossed the Atlantic from the east he passed around South America crossed the Pacific, discovered the Philippine Islands, and went home around the lower end of Africa thus completing a trip around the world. This trip was made less than four hundred years ago, yet when the explorers arrived at their home country they were astonished to find that they carried a date on board their ships which was a day earlier than the home date. It was soon found that no mistakes were made on the log books as to the time records and that the home calendar was certainly correct. The explanation of this seeming impossibility was soon forthcoming, and our date line was born in fact.

As no one wanted the line near his home or country, it was put to the most out-of-the-way place possible, where it still stays. The 180th degree meridian is in theory where each new civil day is born, but in practice it has never been strictly adhered to. Fig. 1 diagram 4, shows its location with the deflections of practice as they now exist on the official map at Washington. This map was made by the Hydrographic Office of the United States to illustrate its replies to a set of questions sent by the writer. The map, together with the questions and the answers, will be found on a recent Pacific chart issued by the Navy Department. To describe the line, commencing at the northern end, it will be seen that the first deflection of practice is to the east, to give the tip of Siberia the same date as the rest of the Russian empire.



1 Theoretical date line. 2 Date line when Alaska took date of Russia and Philippines took date of Spain. 3 Date line after purchase of Alaska and Philippines took Asiatic date. 4 Present international date line.

**Fig. 1.—The evolution of the international date line.**

Then after the line passes through Bering Strait it bears to the west, crossing the true line of 180 deg. and far enough beyond it to take in all of the Aleutian islands to the American date, after which it turns back to 180 deg., where it stays until it crosses the equator a few degrees, at which point it again deflects eastwardly to give the Tonga islands the date of Australia. The line then returns to the 180th meridian and continues on that line to the south pole.

The foregoing is the "international date line" of practice at the present time, but in former generations the deflections were considerably greater, as for example the one shown in the second diagram of Fig. 1. In this date line Alaska was taken into the day of Russia, to which empire it formerly belonged. The line then took a westerly sweep of thousands of miles to take the Philippine Islands under the date as written in Spain. This latter wide deflection was afterward turned back or corrected by the action of the Governor General of the Philippines when he decreed that December 31st, 1844, be reckoned as January 1st, 1845, to bring those islands into accord with the date of the countries east of the Cape of Good Hope. When Alaska was acquired by the United States, the date line was transferred west of that territory or into Bering Strait. These two radical changes made the line of practice look more like the third diagram in Fig. 1. Refer to Fig. 2, which is intended to show the entrance of time on our globe. The picture illustrates a mechanical delivery of our civil day, month, year, or century by means of an equatorial tape. Let us assume that the earth is stationary and that this tape enters and departs under the date-line rollers as shown. If the tape had a speed of about 1,040 miles per hour and was properly marked in hours, days, months, etc., it would show just how our civil day enters the earth and progresses around it with a constant motion. The illustration shows the front end of the twentieth century as having completed 18 hours of its first day on earth, leaving only 6 hours of the nineteenth century to glide toward the line and off, to no one knows where. The front end of January 2nd will have reached the earth's time door to enter it just as December 31st steps out, as it were. Then we have the twentieth century all over the earth with January 1st reducing its equatorial width at the rate of some 17 miles per minute and January 2nd growing broader at the same velocity. This of course is assuming that time is entering normally and not by the arbitrary intermittent steps that we will call the twenty-four way stations of our civil day. This latter system is in successful operation in the United States and two or three other leading nations, China being one of the more recent converts to the hourly zone system.*

Fig. 3 shows the earth with the hourly time belts or zones outlined from pole to pole. The lines drawn are 15 deg. apart and represent the boundary lines of those zones and not their centers. Fig. 4 is the same arrangement as viewed from the north star. In both illustrations the United States are outlined in approximately the correct location, so as to show the theoretical boundary lines of the hourly zones as applied to that country. Now in these two illustrations let us assume that the system has been adopted in all parts of the world. Commencing with the prime meridian at Greenwich as the center of a zone bounded by lines 7½ deg. east and 7½ deg. west, the completion of such a set of lines would give us just what is drawn and what our United States are actually using in theory. To illustrate mechanically the delivery of time on this plan, our equatorial tape is intermittent in its action, that is to say, it jumps 1,040 miles and then stands still for an hour, which means that on the twenty-fourth jump on any day of a given name, that

(Continued on page 367.)

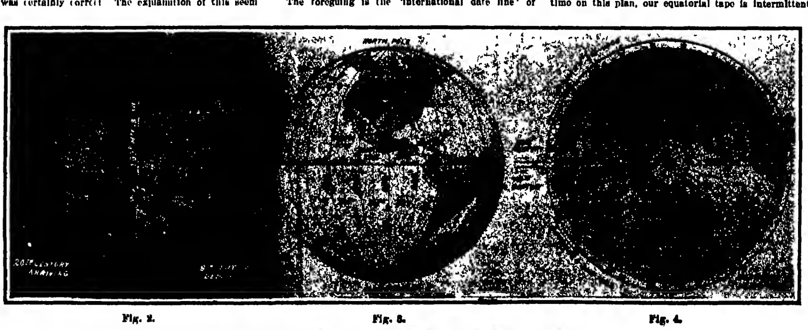


Fig. 2. Fig. 3. Fig. 4.

How the twentieth century was ushered in—a mechanical parallel.

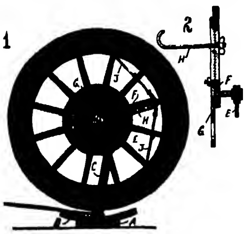
OUR CIVIL DAY—ITS ARRIVAL ON AND PROGRESS AROUND THE EARTH.

* Since writing this article it has come to my notice that Chili of South America has given up local time which was 17 minutes ahead of United States eastern zone and, to quote the Horological Journal, the Chilians were enabled to live the same 17 minutes twice over. The change was accomplished by firing a gun at 12:17 A. M. on a given day and calling it midnight. This means that New York city or Washington, D. C., may cable messages to Chili without having to take note of any difference in time.

# Patent Department

## NOVEL AUTOMOBILE PUMP

Pictured in the accompanying engraving is an interesting form of pump, that may be used for inflating an automobile tire. The device is arranged to be operated by the automobile itself It consists of a base *A*, on which is mounted a jack used to raise an automobile axle so that the wheel will clear the ground The base *A* carries a shoe *B*, which is designed to assist in positioning the automobile wheel with respect to the pumping device before the jack is operated to raise it The pump is indicated at *C*, and is mounted to rock on a bolt *D* The pump piston *E* is connected to the automobile wheel by a device shown clearly in the cross-sectional view (Fig.

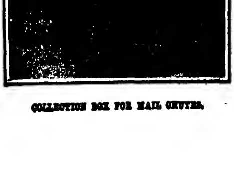


NOVEL AUTOMOBILE PUMP

2) A slotted plate *F* is provided with teeth adapted to engage similar teeth on a slotted plate *G* The plate *G* is provided with a crank pin, to which the piston rod *E* is connected The plate *G* is provided with an apertured extension, adapted to fit over the axle of the automobile wheel The plate *F* is attached to one of the spokes of the wheel by means of a hook *H* while a pair of hinged braces *J* are used to connect it with two more spokes of the wheel In this way a rigid connection with the wheel is secured By loosening the thumb nut on the hook *H* the plate *F* may be moved up or down on plate *G* so as to adjust the parts to wheels of different sizes. The distance from the crank pin to the center of the wheel however, is fixed In use the automobile engine is operated to rotate the wheel, and this action carries the piston up and down in a cylinder, the latter rocking back and forth to accommodate itself to the lateral throw of the crank pin A flexible tube connect the pump with the tire that is to be inflated By this arrangement a tire may be inflated very rapidly, and the inflation carried to a further degree than is possible by the manual operation By using a speed attachment of any of the well-known types, the bursting of tires due to excessive pressure may be avoided This inventor of this automobile pump is Dr Richard A. Goeth of San Antonio, Texas.

## COLLECTION BOX FOR MAIL CHUTES.

Collection boxes at the termini of mail chutes are frequently filled to such an extent before the mail is removed that when the collection is made the mail tumbles out of the box on opening the box door and falls to the floor in spite of every precaution taken by the collector To better this bothersome condition a box has recently been devised which is provided with a platform having foldable side walls that permit the platform to swing downward when the door of the box is opened and serve to prevent the mail matter from falling from the box. The construction of this



COLLECTION BOX FOR MAIL CHUTES.

box is clearly shown in the accompanying engraving Fig 1 shows the box door open with the platform *A* swung down horizontally The platform is provided with two side wall plates *B* rigidly secured thereto and a series of sector shaped plates *C* Near the forward edge of each of the plates *B* and *C* is a groove *D* adapted to receive a pin mounted on the adjacent plate, while at the opposite ends the plates of each side wall are mounted on a common hinge pin This permits the side walls to close up somewhat after the manner of a fan to the position indicated in Fig 2 The innermost sector *C* is provided with a lug *E*, which engages a lip formed at the top of the box and limits the outward swing of the platform *A* To prevent the letters from dropping between the sector plates the top of the box is provided with two guards *F* which extend below the upper edge of the plates In use when the platform is lowered the letters in the box will tumble out through the door opening and will be caught by the platform and side walls The inventor of this collection box for mail chutes is Mr R E Edwards, care of T J Kelly, 29 South Eleventh Street, Lincoln, Neb.

## A NEW SOUNDING BOARD FOR PIANOS.

The soul of a piano is its sounding board That sounding board is composed of wood carefully selected and carefully seasoned, so that it will remain constant in quality for the many years during which a piano is used. It is arched or crowned against the pressure of the strings so that the strings and the sounding board may vibrate in harmony As the piano ages the sounding board flattens. In an upright piano this flattening is accompanied by "buckling back" or cracking The result is that hard metallic so-called "tin panny," tone so characteristic of old pianos It is obvious that if some means were provided for permanently arching the sounding board against the pressure of the strings, the piano ought to maintain its tone for years without any tendency of the sounding board to sag

The attempt has been made frequently Some success has been attained in grand pianos by the employment of tension rods radiating from a center hub to the sounding board rim, but so far as we are aware no one has ever successfully equipped the upright piano with a sounding board so constructed that it would not lose its arch in time A sounding board of this type which has been successfully applied to an upright piano has recently been invented by Mr Frank B Long of Los Angeles Cal and is illustrated in the accompanying engraving

What Mr Long has done can best be understood

TENSION DEVICE FOR PIANO SOUNDING BOARDS

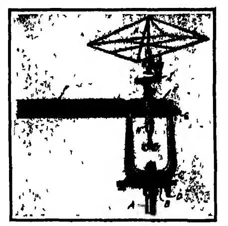
when we consider the true function of the sounding board of a piano The sounding board serves to sustain and amplify the tone produced when a hammer strikes the strings. Mr Long has increased the tone sustaining and amplifying quality of the sounding board by flexible reinforcing means interposed between the sounding board and the sounding board frame, thus equalizing the flexibility of the sounding board and at the same time maintaining its relation to the sounding board frame, so that the greatest possible vitality of the sounding board is insured From the accompanying illustration, which shows the front of an upright piano with Mr Long's sounding board in position, it will be observed that the edge of the sounding board is subjected to pressure from screw posts interposed between the edge of the sounding board and the heavy back frame The pressure is exerted in such a manner as to cause reflection and condensation of sound waves in accordance with the principles suggested by Helmholtz in his work on "Sensation of Sound" Besides creating this reflecting effect, the pressure post serves the additional purpose of maintaining the crowned sounding board in its original form The back frame supporting the sounding board is reinforced by diagonal tension rods placed across each corner, as shown in the illustration

The edge of the sounding board is rabbeted and glued into a continuous laminated rim built up of hard maple veneers or layers so as to produce an exceedingly strong construction, which, however, is sufficiently flexible to yield under the pressure posts, with a view to equaling the outward pressure on the sounding board resulting from the stretching of the strings over the surface By the use of screw pressure-posts, any shrinkage or expansion of the sounding board and the rim can readily be equalized so as to preserve the tone and even to amplify it The arrangement is such that a proper reflection of the vibrations of the sounding board is obtained, as the strain on the sounding board by the strings is equalized to reflect the tone

As a result of this new combination of sounding board rim and pressure posts a small upright piano can produce a tone which is comparable with that of a small grand piano, and the full round tone of the new upright piano is preserved because the sounding board is maintained in its original arched position

## EDUCATIONAL APPLIANCES FOR DISPLAYING OBJECTS.

In the instruction of projection mechanical drawing, descriptive geometry, etc, it is important to be

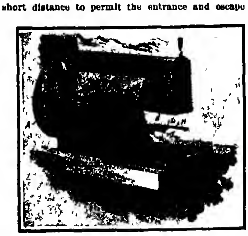


EDUCATIONAL APPLIANCES FOR DISPLAYING OBJECTS.

able to show students a skeleton model of an object, large enough to be seen by an entire class, and which will show front and side elevations as well as plan and bottom views. Heretofore this has been done by using a glass box within which the object was placed, or by using wire screens for the sides of a box, which permitted the teacher to chalk mark the outline of the object An improvement on this system is offered by the invention illustrated herewith It consists of a stand provided with axes that have automatic stops at quarter revolutions to arrest the model in various positions The apparatus comprises a vertical shaft *A*, on which is mounted a table *B* that carries a support *C*, provided with a pair of upwardly extending arms The support *C* has in its lower face four recesses adapted to receive a spring pressed stop pin *D* The recesses are positioned at quarter revolutions of the support. Mounted in the arms of the support is a shaft on which are secured the square blocks *E* and *F* The block *E* is formed with four recesses adapted to receive the pin *G* The blocks are adapted to receive a clamp *H* that carries the display stand *J* Model *K* is shown supported on the stand The display stand may be moved about on three axes which are fitted with index wheels so as to incline or turn the model about to any desired angle The inventor of this educational appliance who is Mr Hermann Haustein of 2019 Mohawk Street Chicago, Ill informs us that he has used this display apparatus effectively in his own classes

## IMPROVED DETACHABLE WINDOW VENTILATOR

The ventilator which is illustrated in the accompanying engraving may be detachably secured to the window casing so that the window may be opened a short distance to permit the entrance and escape of

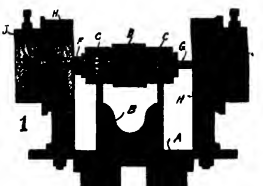


IMPROVED DETACHABLE WINDOW VENTILATOR.

air Furthermore, the ventilator is provided with an automatic damper, which acts to prevent the entrance of unusually strong currents of air and is fitted with a baffle which serves to keep out rain or snow The casing of the ventilator, as indicated at *A*, is quadrant shaped in section, and is fitted into a bracket at each end secured to the window casing. The lower edge of the casing is provided at *D* with a lip that engages the sill of the window Extending lengthwise of the ventilator is a bar *C*, which is formed of sheet metal bent back upon itself to form a holder for two packing strips *D* and *E* which extend in opposite directions The packing strip *D* is adapted to fit against the sash of the window, while the other strip serves as a buffer for the damper At the opposite side of casing there is a vertical extension *F* which serves as a baffle The screen *G* stretches from the base of this extension to the bar *C*, and serves to keep out foreign bodies that may be drawn into the ventilator by the blast of air The damper is indicated at *H*, and consists of a plate bent back upon itself at *J* to form a reinforcing bar while the inner end *K* is weighted so that the damper will normally come to a balance on the axis *L* When the window is raised the damper swings to the horizontal position as indicated, but if a strong draft blows through the ventilator it will strike the under side of the inner part of the damper, lifting it up until if the wind is strong enough, it strikes the buffer *E* When the window is closed it positively closes the damper by bearing against the outer section *H* The brackets on which the casing is mounted are extensible so as to permit of using a standard length of ventilator with windows of different size Each bracket is formed with a spring extension *N*, provided with a lug which is adapted to engage a stop pin on the window sash, and prevent the window from being raised too high Should it be desired to raise the window further it is a simple matter to withdraw the spring catch *M* The inventor of this ventilator is Rulla M Hill care of the Economy Ventilating Co Metropolitan Tower, New York.

### TENONING MACHINE.

The machine pictured herewith is designed to cut cylindrical tenons on the end of a wooden slat, particularly for use in window blinds. Window blind slats

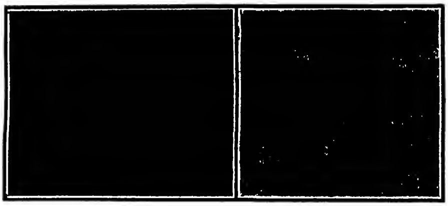


TENONING MACHINE.

usually are provided with a single central tenon, but there is another type in which two tenons are used, and sometimes the slat is provided with three tenons. The machine is designed to form any of these types of slats. It consists of a base *A* provided with a central bracket *B* formed with two bearings *C* in which is mounted an arbor shaft. The arbor shaft is provided with a pulley *D* between the bearings, and may be fitted with tools, such as shown at *F* and *G* which depend for their form upon the nature of the work which they are to do Opposite each end of the arbor shaft is a pedestal *H* fitted with a head *J* In our illustration the head is broken away at the left hand side of the machine to reveal the interior construction A cross-sectional view of the head is also shown in Fig 2 The head is formed with an interior web *K*, and the web is formed with a pair of channels that intersect at the center of the head At the upper end of the vertical channel and at one end of the horizontal channel is a spring such as shown in Fig. 1, which may be adjusted by means of the screws *L* and *M*, to bear against the work which is placed in the slot. It will be understood that the head *J* is revoluble within the pedestal *H* The pedestal is connected to the base *A* by means of a pair of bolts which pass through slots in the base plate thus permitting of a lateral adjustment In use a slat is inserted in one of the channels in the web *K*, and the end of the slat is brought into contact with one of the cutters on the arbor shaft The pedestal is adjusted laterally so that the center of the slat is out of alignment with the axis of the tool and then when the slat is fed against the tool and the head *J* is revolved a circular tenon will be cut in the end of the slat. If a large tool is used all the wood will be cut away except a single tenon, but if a smaller tool is used a central tenon may be cut, leaving enough wood projecting at each end of the slat to form two more tenons. In this way a slat with three tenons can be formed, and by properly choosing the size of the tool and laterally adjusting the pedestal the slat may be formed with two tenons. The inventor of this slat tenoning machine is Mr José Ojanguren, Calzada del Monte, No 356, Havana Cuba.

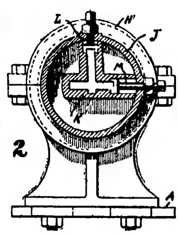
### IMPROVED JACK BLOCK.

When the journal bearings or brasses of a railroad



IMPROVED JACK BLOCK.

car become worn it is necessary to lift the journals by means of jacks so that the brasses may be removed from the car axle, and be replaced with new ones When operating the jack it sometimes happens that the car wheel is lifted with the journal and derailed The purpose of the invention illustrated in the accompanying engraving is to provide a device which will hold the wheel down while the journal is being lifted, and form a level surface for the jack to rest upon The jack block is preferably made of malleable cast iron or steel, and is constructed in the form of a grating with the edges scalloped or corrugated so as to insure lightness without unduly weakening the stucture At one end the block is provided with an extension *B*, terminating in a toe *C*, which is adapted to fit over the rim of the car wheel. The jack block is rested on one of the sills of the ties of the railroad, and the jack is seated on the upper face of the block, close to the extension *B* When



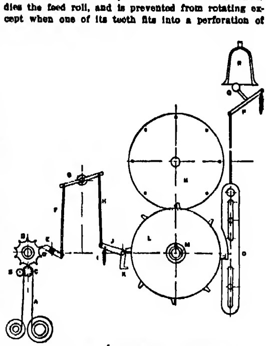
the journal is jacked up the toe serves to hold the wheel to the rail, relieving the upper journal bearing of the weight of the car and permitting the wedge and brasses to be removed For convenience in carrying the block about a handle *D* is arranged at each side of the body of the block, the location being such that the block is balanced when lifted The inventor of this jack block is Mr James Allen Gray of Cœur d'Alene, Idaho.

### RINGING CHIMES BY PERFORATED MUSIC SHEETS.

One of the pioneer inventors of the automatic piano player, Mr John McTammany of New York city, has devised a system of ringing chimes of bells by perforated paper music sheets, such as are employed in piano-playing mechanisms. Mr McTammany's scheme was evolved as part of a huge memorial to be erected to the memory of the men who fell in the civil war The memorial assumed the form of a monument in which each State was to place two bells. To ring so extensive a chime by hand would obviously be a task involving superhuman muscular power, Even the present mechanical and electrical methods would probably fail because of their complexity Hence, Mr McTammany devised the very ingenious system which is here illustrated

The perforated music sheet *A* is guided by a roll *B*, and passes over a grooved roll *C* The pins of a driving wheel *D* are adapted to engage the perforations of the music sheet *A* The pin wheel *D* is operatively connected by means of a dog *E*, a connecting rod *F*, a rock shaft *G*, a connecting rod *H*, and an angle tripper *JK*, with a primary star wheel *L*, which meshes with the secondary star wheel *N*. The primary and secondary star wheels *L* and *N* are loosely mounted on collars on their respective shafts, and are housed between separators *M* in such a manner as to prevent them from shifting thereon, yet leaving them free to rotate with the shaft whenever it may be necessary for them to do so to ring the bell-ringing mechanism. The star wheel *L* is provided with teeth on its periphery, which teeth are adapted to engage rods projecting from the star wheel *N*, whenever the star wheel *L* is released by the angle tripper *JK* The teeth of the star wheel *L* engage a slide *O*, connected with a retractile spring-controlled clapper *PQ*, which rings the bell *R* The several shafts illustrated are geared together in such a manner as to cause the several parts to co-operate in definite order

A tooth of the wheel *D* having entered a groove of the feed roll *C* through a perforation in the music sheet *A*, the wheel *D* turns on its shaft. In so doing it engages the dog *E*, which in turn through the connecting rods *F* and *H* trips the angle tripper *JK*, thus releasing the secondary star wheel *L*, which, by the friction of its shaft, rotates into engagement with the slide *O*, thereby pulling the slide down and withdrawing the clapper from the bell When the slide is released by the teeth of the star wheel *L*, the retractile spring of the clapper is released, so that the clapper deals its stroke and rings the bell as the parts return to their normal positions. The wheel *D* straddles the feed roll, and is prevented from rotating except when one of its teeth fits into a perforation of



RINGING CHIMES BY PERFORATED MUSIC SHEETS.

the sheet and into the grooved roll, which turns the primary star wheel one degree.

The playing of the bells can be governed by clock mechanism, so as to strike the quarters and the hours and to play airs at stated intervals.

A new form of mercury interrupter has recently been invented in which there are no reciprocating parts, but the interruptions are produced by a ripple formed in a stream of mercury The mercury is contained in a revolving vessel within which a contact piece is fixed. The mercury is thrown by centrifugal force to the inner periphery of the vessel. At one point the stream of mercury is obliged to pass over a deflector, producing a ripple or wave, and the contact piece dips into the mercury stream at this point as it revolves with the vessel. The frequency of the interruptions may be varied by making the deflector revolve slowly in the same direction as the vessel is revolving, or in the opposite direction, or letting it remain stationary.

# It is Easy to make advertising

**claims for cars; but to make cars that will make good the claims is hard.**

**We ask automobile buyers to do this: After the advertisements have attracted your attention, then in fairness to yourselves and all the manufacturers, compare the cars *point by point.* That is all we ask.**

There are Chalmers dealers in all parts of the United States—more than 200 of them. We suggest that you get in touch with the one nearest to you at once. Let us send you his name if you do not know him.

## Chalmers "30" $1500

Judged by price alone you might as well buy some other car as a Chalmers: $1500 is simply $1500—no more in one bank than in another, no more in bills than in coin, no more in your pocket than in another man's.

It is only when you begin trying to buy something with your money that the sense of value enters your mind.

Your $1500 is worth more than another man's $1500, if at all, only because you are able to buy more with yours than he can buy with his.

We believe that when you buy a Chalmers "30" your $1500 becomes worth more than $1500 invested in any other car. Careful investigation will convince you of this fact.

Please remember you are not buying a *price* or an *advertisement:* you are buying a *car.* Therefore examine the *car* on its merits.

If you investigate thoroughly a Chalmers will be your *first choice,* if you are able to get a delivery in your territory.

* * *

It is difficult to get more in a car, at any price, than you can get in a Chalmers "Forty" at $2750. The "Forty" has all the power one can want, the quality to endure, beauty of line and luxurious finish. Seats for seven if desired. **Catalogue "R" on request.**

# Chalmers Motor Company

**Licensed under Selden Patent**

**OUR SEACOAST DEFENSES.**

(*Continued from page 301.*)

put out of action, there are emergency range finders installed on the flank of each battery. This range finder is the Barr and Stroud 9-foot, self-contained horizontal base type. In case these are put out of action ranges must be determined by means of buoys or from observation of fire.

The firing of mortars is far more difficult than that of guns. The detachments at the mortars are completely concealed. These weapons attack the decks of ships, and when fired their location cannot be discovered. They are set for elevation in practically the same manner as guns, but their direction, instead of being set on sights, is accomplished by laying the mortar on an azimuth circle. In other words the mortar is set for an elevation corresponding to the range, and at an angle of direction equal to the azimuth of a predicted position of the target corrected for wind drift, travel, etc. Many authorities considered mortars in past years to be so inaccurate as not to authorize their construction, but within recent years the results of tests and the records of target practice have shown that mortars are of immense value to seacoast fortifications. Several companies in our coast artillery have made as high as 80 per cent hits at ranges of six and seven thousand yards when firing on a moving target having a speed of seven or eight miles an hour and when firing but one mortar at a time. Mortars have a particularly great value in repelling a reconnoissance in force as they can be fired with impunity without disclosing their location.

Another important arm, if not the most important arm of defense in the coast artillery, is that of submarine mines. These weapons are designed to repel an attack when the hostile fleet attempts to come in during a fog or when the guns have been put out of action. The system is so designed as to render these mines harmless to friendly ships and to be under such perfect control of the mine commander as to permit their being fired either by contact or judgment. The electrical principles involved in the control and firing of submarine mines is kept a secret. Ten years ago it took almost two weeks to plant a group of mines. To-day, by the use of mine planters, a harbor can be completely blocked within twenty-four hours.

The work that will devolve upon coast artillery troops in time of war will be of the most trying and patience-racking nature.

It is presumed in making this statement that no fleet commander would attempt an open attack or "run by" in broad daylight but would await the early dawn in a partial fog, when searchlights are useless and the spirit of the men at the guns at its lowest ebb. He would, without doubt, wear the gunners and cannoneers out and try their patience by making many sorties and feints during late hours of the night and early morning before making his final attack. He would also if possible await his attack until cold weather set in and snow had fallen, knowing how dispiriting ice and snow are to soldiers living in tents, as they would have to do during war.

In the harbor of New York, for example, if war were declared all coast artillery would have to live in tents immediately in rear of the guns.

Would it not tend to breed discontent and dissatisfaction among soldiery if they were required to answer "call to arms" every hour during the night for about two weeks in bitter winter weather?

This is the work the coast artillery will have to do when it is called to defend our country's ports from the invasion of a foreign navy.

It will be then that the "brave the

active, and the vigilant" will be called upon to show their true colors and "make good."

## OUR CIVIL DAY.

(Continued from page 302.)

particular day stays on the world (the entire world) for an exact hour

Let us trace the front end of the twentieth century by this system of progress. We again show it as having reached its eighteenth hour on earth as in the former illustration. That is to say, it has reached the 90th meridian west of Greenwich, or central time, but as central time covers 15 deg. of longitude we have sent the head end of our century to 97½ deg. west, making it arrive there half an hour too soon We then compel it to stay there until it is a half hour late. Then it takes another jump to mountain time, which lands the 1st of January, 1900, at the 112½ deg. W meridian, and so on. By adhering strictly to the system, let us note what happens when January 1st reaches 180 deg. Of course it must cover the 15-deg. zone, the center of which is 180 deg, thus transferring the "international date line" to 172½ deg. east of prime The theoretical date line is thereby moved 7½ deg ahead of the 180-deg true line.

Before proceeding with our examination of the ragged edge of time, which local convenience demands on the hour zones or way stations let us glance back at the first diagram of Fig 1 and look at the theoretical line where our civil day enters, then at the former practice in regard to Alaska and the Philippines, then at the line where these two countries changed places, as it were, and finally at the line of practice as now in use (1910). The deflections of practice which appear on this terminal station of time also appear in a constantly changing and more exaggerated form on the way stations (hour zones) We have noticed how irregular the front end of the twentieth century was when it entered the earth Now refer to Figs. 3 and 4 and see what happened to it when it progressed around the earth as far as New York city, that is to say when it reached 75 deg west (the eastern time zone) The dotted outline of the United States enables us to see that Palm Beach, Florida, should be "ringing in" the new year and century in unison with New York city Not so Palm Beach is still on the nineteenth century calendar, and will be for another hour The beach does not belong there, but as the railway managers voted it into central time in 1883, it is still held there by steel rails just as rigidly as the Tonga Islands are put in "to-day" by the steamship lines when they really belong in "yesterday," and as the more westerly members of the Aleutian Islands are kept in "to-day" when they should be in "to-morrow"

I once referred to these zone lines to a friend as imaginary "Imaginary" said he, "I will never forget the time I passed over one when going to California from New York My appetite was running a bit ahead of time, and I was impatiently waiting for the dining car to open up at twelve noon, as the time table said it would. The porter entered my car, and instead of the musical sounds of first call for luncheon on a dining car he shouted "Set your watches back one hour." If his train had reached El Paso, Texas, under similar circumstances, it might have left the tracks. That is the point where the western time zone overlaps to such an extent that it actually meets an easterly deflection from the Pacific zone. The porter would have then called, "Set your watches back two hours."

To persons who have not looked closely into this complicated subject, the first question that comes to their lips is, Why not keep the date line and zone lines straight in practice as well as in theory? Suppose that you live on Main Street, Machiasville, Maine, where longitude 67½

*(Concluded from page 307)*

dog west of Greenwich passes right through your front parlor. You will therefore set your hall clock an hour forward and let your little mantel clock stay as it is now. Very soon you would like to deflect the line enough to at least pass outside of the walls. Then you see visions of a late delivery of milk for your breakfast, and request that the line sweep in the milk depot, then the railway station, and finally that your office be kept in the same zone of practice. Take another glance at the eastern time zone. That little bump on its edge was put there, not only to keep the line out of your parlor, but outside of the State of Maine. The mere fact that you and most of your neighbors were unaware of this deflection east of Maine is a proof that the line benders did their work well. If a very large percentage of the people of the United States knew that their zone lines were bent, it would be time to bend them into some different form.

As some readers might overlook the fact that the astronomical day begins and ends at Greenwich at noon, 12 hours later than the beginning and ending of the civil or common day (the day we sleep and eat and work by), we should make it plain that all the illustrations and remarks apply to the civil one. The astronomical day is a clean cut straight line affair that needs no adjusting to practice. The users of this kind of a day do not try to thrust its date line aside. The observatory at Greenwich was built right on this line and to make it more realistic a bronze tablet is set in stone with prime meridian (Zero Degree) engraved on it so that it may be seen and felt by those who visit the observatory.

### The Energy of a Coiled Spring.

The old question of what becomes of the energy of a coiled spring placed in sulphuric acid cropped up again before the Western Society of Engineers during a discussion on the conservation of energy. Dr. Steinmetz gave this explanation on that occasion.

The heat produced by the chemical action in a coiled spring when dissolved, is greater by the amount of energy stored in it than if the spring were not under pressure. The amount of energy which is stored in compressing the spring in heat measure is so insignificant compared with the energy of solution that one cannot measure the difference calorimetrically but one can prove that the compressed spring produces a greater heat in dissolving than the uncompressed spring, in an indirect manner. The measure of the chemical energy is the electrical potential difference. If one dissolves iron in an acid and the iron is under strain partly compressed, partly not one finds an unequal corrosion due to local current between the different parts of the iron. If there is a local current it means that the different parts of iron have different potential differences against the electrolyte, that is different chemical affinities, and the part under strain is dissolved first, showing a greater potential difference and thus a greater heat produced in its solution. Thus, if only a part of the spring were compressed, the other part not, the compressed part would dissolve first in the sulphuric acid by the local current circulating between the two, showing that its solution gives more energy than that of the uncompressed part.

Thomas Edison recently took out a patent on an improvement in his storage battery. According to the patent the active material for alkaline storage batteries is impregnated with an oxygen compound of bismuth, by first soaking the mass in a solution of a bismuth salt, then subjecting the material to centrifugal action, and afterward drying. The dried mass is then heated in a caustic alkali solution, and finally washed to remove the excess of alkali.

## PATENTS FOR SALE

FOR SALE—U. S. and Canadian Patent on cake mixing machine of original construction adapted for bakery and family use. A large field for an enterprising party. Address Fred. Seifert, 541 Eleventh St., Oakland, Cal.

Inquiry No. 8918. For manufacturers of "Wydts Electro Catalytic Sparking Plug."

FOR SALE—Patent No. 932,751. New egg candling and packing machine which candles eggs and packs them in standard egg cases in one operation. Big demand for a machine of this kind. For further information address H. Pieper, Colline, Neb.

Inquiry No. 8987. Wanted the manufacturers of the Van Winkle Woods & Sons and the Waber power meters.

OUTRIGHT SALE OR ON ROYALTY, U. S. Patent No. 936,791, Canadian Patent No. 125,011. Envelope with special flap construction which after sealing it being impossible to gain access without leaving evidence of the fact that the envelope had been tampered with. For particulars address N. McDonald, Irish Cove, Nova Scotia.

Inquiry No. 9011.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

## WANTED

A THOROUGHLY UP-TO-DATE FOREMAN for a hustling automobile repair shop. None but a sober competent man need apply. Also two machinists skilled in automobile repairing. Youngs & Co., Newburgh, N. Y.

Inquiry No. 9016. Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## HELP WANTED.

MECHANICS AND INSTRUMENT MAKERS, first class only, wanted at once. State references and wages desired. V. W., 251-253 Broadway, New York.

Inquiry No. 9027. Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

## SITUATIONS WANTED.

COPPERSMITH expert, understands the business thoroughly. Able to work different kinds of metal, capable of taking charge of shop, desires to make a change. Address Metal Worker, Box 773, N. Y.

Inquiry No. 9030. Wanted catalogues and all information on machinery for braiding straw for manufacturing straw hats.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9038.—Wanted the address of the Chipman Electric Purifying Co.

Inquiry No. 9043.—Wanted the address of Farney Safety Razor Co.

Inquiry No. 9053.—Wanted address of firms who install plants to manufacture nitrogen.

Inquiry No. 9055. Wanted address of parties interested in Log Cleaning Machines.

Inquiry No. 9060.—Wanted to buy machinery to manufacture seed corn racks.

Inquiry No. 9066. Wanted complete outfit for export for making rice-flakes and wheat-flakes.

## SALE AND EXCHANGE

FOR SALE.—Engine lathe. Our regular $75.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $45.00. L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9069.—For the address of firm making chain cloth, something like ladies' purses are made of.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9071.—Wanted, the address of parties making moulds for large concrete vases for flower pots.

Inquiry No. 9072. Wanted machinery for making fine chains, such as used by jewelers, etc.

Inquiry No. 9073. Wanted, machinery to manufacture cocoanut oil; also the crude material.

Inquiry No. 9074. Wanted to buy old model locomotives or steamboats, such as were exhibited with nickel-in-the-slot attachments in ferry houses, etc.

Inquiry No. 9075. Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted the address of parties in Canada who could make a safety razor.

Inquiry No. 9077. Wanted the address of manufacturers that make small articles of wood, such as checker boards, etc.

Inquiry No. 9078.—Wanted the address of manufacturers of sewer pipe, made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9079. Wanted, parties to make a special steel plate rolled for "angle bars," in large quantities.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9082. Wanted, the address of firms manufacturing small beer brewing plants from 75 to 100 gallons a day.

Inquiry No. 9084. Wanted the address of manufacturers of Irwin portable bath tubs.

Inquiry No. 9085. Wanted to buy longitudinal hollow perforated tubing.

Inquiry No. 9086. Wanted to buy a pine wood peeler.

Inquiry No. 9087.—Wanted a machine for hardening hack saw blades; also a machine for setting same when they have been toothed.

Inquiry No. 9088.—Wanted the address of manufacturers of family sized peanut pulverizers for making peanut butter.

Inquiry No. 9090.—Wanted manufacturers of suspender and supporters supplies, also patent adjustable bachelor buttons.

Inquiry No. 9093. Wanted the address of some firms who manufacture permanent lamp wicks.

Inquiry No. 9094.—Wanted address of The Thomas Arithometer Company, also Burkhart Arithometer Company.

Inquiry No. 9095.—Wanted, name and address of the manufacturer of the duplex revolving pencil sharpener.

Inquiry No. 9096.—Wanted, the address of manufacturers of spiral welded pipes, possessing great strength.

Inquiry No. 9097.—Wanted, address of makers of impulse water wheels.

Inquiry No. 9098.—Wanted, name and address of the manufacturers of the ususiser.

Inquiry No. 9099.—Wanted address of manufacturers of machinery for making wire cables.

Inquiry No. 9101. Wanted addresses of manufacturers of a dip or magnetic needle, for exploring for iron ore.

Inquiry No. 9102.—Wanted, addresses of parties who will manufacture wafer safety razor blades.

Inquiry No. 9103. Wanted addresses of concerns manufacturing composition materials to take place of hard rubber.

Inquiry No. 9104.—Wanted, addresses of manufacturers under the name of A. O. Co. Standard.

Inquiry No. 9105.—Wanted manufacturers of cheap gums and resins.

Inquiry No. 9106.—Wanted, addresses of cotton dealers who can furnish cotton material for manufacturing envelopes.

Inquiry No. 9107.—Wanted, addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

Inquiry No. 9108.—Wanted the addresses of manufacturers of cardboard.

Inquiry No. 9109.—Wanted addresses of the manufacturers of the Dion Desk Clock.

Inquiry No. 9110.—Wanted to buy machinery for reducing old tin cans, so that they may become a source of revenue.

Inquiry No. 9111.—Wanted to correspond with manufacturers who furnish nut-cracks, or similar articles.

Inquiry No. 9112. Wanted sample small dry vacuum pump about 6-inch diameter cylinder inside, high temperature metal packing.

Inquiry No. 9113.—Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

Inquiry No. 9114.—Wanted name and address of manufacturer of the Auto Lantern Globe. Fits all lanterns.

Inquiry No. 9115.—Wanted a machine for making pen nibs, similar to Wm. Mitchell's G. & J. nibs and Waverly nibs.

Inquiry No. 9116.—Wanted machines to make wire netting 3 inches wide by 25 yards long and for galvanizing the wire netting as it is finished.

Inquiry No. 9117.—Wanted names and addresses of the manufacturers of pedometers.

Inquiry No. 9118.—Wanted, a muffler for a gasoline engine, built upon the principle of the Maxim silencer, recently brought out for use on rifles.

Inquiry No. 9119.—Wanted, name and address of the manufacturer of Rapin bullet-proof cloth.

Inquiry No. 9120.—Wanted the address of the Ideal Fuel Feeder Co.

Inquiry No. 9121.—Wanted manufacturers of cut stencils for fancy work, sofa pillows, etc., and oil colors and brushes for same.

Inquiry No. 9122.—Wanted, manufacturers of ditching machines used for tiledrains operated by horse power.

Inquiry No. 9123.—Wanted, names of importers or dealers in crude gutta percha and rubber.

Inquiry No. 9124.—Wanted name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

Inquiry No. 9125.—Wanted, name and address of the Just Hatmaker machine for manufacturing milk powder.

Inquiry No. 9126.—Wanted to buy machine for putting up and preparing condensed milk.

Inquiry No. 9127. Wanted, address of L. Dermigny, manufacturer of a family ice machine for $10.00.

Inquiry No. 9128.—Wanted a hand planer for metal working, in which the hand planer is made to be attached to any ordinary bench vise. The vise and the planer are combined to form only one machine.

Inquiry No. 9129.—Wanted, addresses of makers of machinery for paper box factories, or new or second-hand paper box making machinery.

Inquiry No. 9130.—Wanted, parties to manufacture a new patented shell for shot guns.

Inquiry No. 9131.—Wanted information as to how or where I could get a sample of tin ore.

Inquiry No. 9132.—Wanted, manufacturers of a gasoline traction engine with a hoisting attachment; in other words, the machine will be used as a portable stump puller to pull sassafras roots, used in making oil of sassafras.

Inquiry No. 9133.—Wanted manufacturers of floss candy machines.

Inquiry No. 9134.—Wanted a small hydraulic motor, capable of giving about one horse power with a water power of 85 lbs. per square inch.

Inquiry No. 9135.—Wanted, name and address of manufacturers of the Parshall Compressed Air Ice Machine.

Inquiry No. 9136.—Wanted the name and address of a skunk raising farm.

Inquiry No. 9137.—Wanted a device that will braid leather strips for horse whips.

A printed copy of the specification and drawing of any patent in the foregoing list or any patent in print issued since 1863 will be furnished from this office for 10 cents provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York.

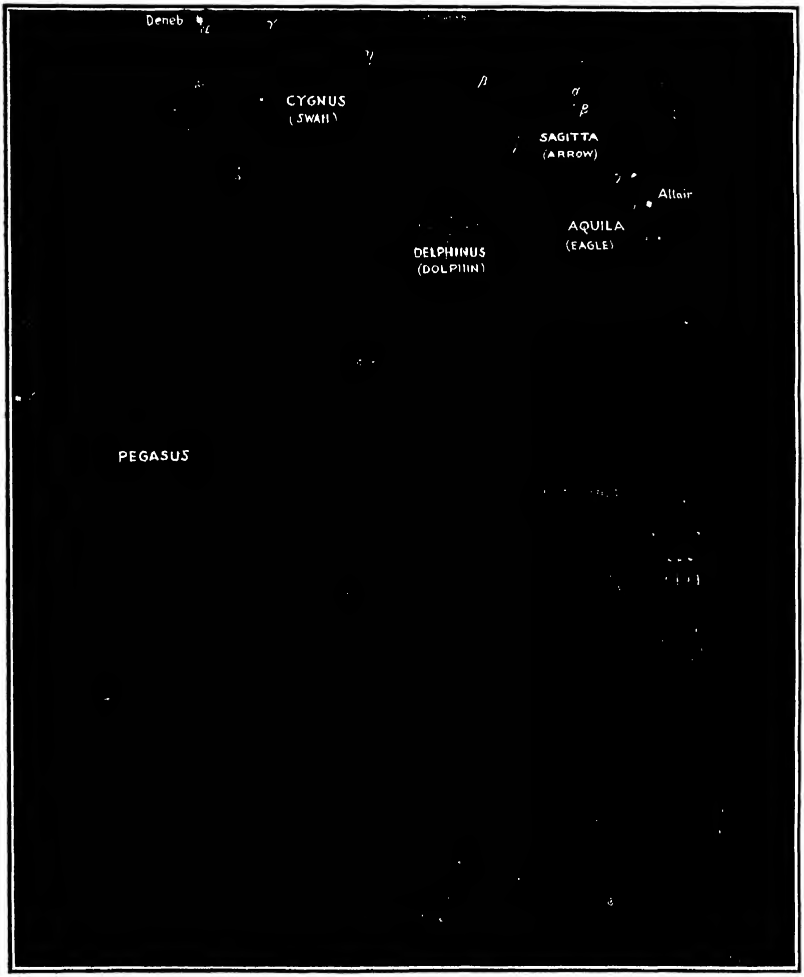
Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

# SCIENTIFIC AMERICAN

[Entered at the Post Office of New York, N. Y., as Second Class Matter]

A POPULAR ILLUSTRATED WEEKLY OF THE WORLD'S PROGRESS

[Vol. CII.—No. 16. Established 1845.] NEW YORK, APRIL 16, 1910. [10 CENTS A COPY, $3.00 A YEAR.]



Halley's comet is now visible to the naked eye in the eastern skies, just before dawn. Its appearance on May 2nd, one hour before sunrise, is here depicted.

HALLEY'S COMET AT ITS BRIGHTEST.—[See page 317]

*TERMS TO SUBSCRIBERS*

Subscription one year $3.00
Postage prepaid in United States and possessions, Mexico, Cuba and Panama
Subscriptions for Foreign Countries $1.50 per year extra.
Canadian postage .75 per year extra.

*THE SCIENTIFIC AMERICAN PUBLICATIONS*

Scientific American (established 1845) $3.00 a year
Scientific American Supplement (established 1876) 5.00 "
American Homes and Gardens 3.00 "

The combined subscription rates and rates to foreign countries, including Canada, will be furnished upon application.
Remit by postal or express money order, or by bank draft or check.
MUNN & CO., Inc., 361 Broadway, New York

NEW YORK, SATURDAY, APRIL 16th, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## THE WORLD'S FAIR OF THE FUTURE

In all probability the city of San Francisco will hold an international exposition, or as it is more popularly known, a World's Fair, to celebrate the opening of the Panama Canal in 1915. If the promoters of the fair are willing to profit by the lessons of former expositions, their efforts will be directed to making the coming fair notable, not for mere bulk and area, but for its compactness and the genuine excellence of its carefully selected exhibits. The trouble with many previous expositions has been that they were big to the point of being wearisome and oppressive. A climax in this direction was reached at the St. Louis Fair, in one single building of which a visitor had to traverse nine miles of aisles if he wished merely to walk past the whole of the exhibits. Whatever may be the ulterior motive, the avowed object of these exhibitions is educational. Therefore, they should contain only the most distinctive and valuable results of the world's scientific, industrial, sociological, and constructive work. And in this connection we would ask whether it is not almost an insult to the good taste and intelligence of the millions that are solicited to enter such an exposition, if a large section of its space is devoted to that cheap form of entertainment which was inaugurated by the notorious Midway Plaisance at the Chicago Exposition. San Francisco will have a great opportunity by breaking away from certain false traditions, to render this, the latest of the expositions, something better than a mere plaything of the real-estate dealer, the side-show man, and the politician.

## GYROSCOPIC EFFECT OF REVOLVING AEROPLANE MOTORS.

There were certain conditions in the recent fatal accident to Le Blon which suggest that the gyroscopic effect of the motor may have contributed to the disaster. He was using a light monoplane of the Blériot type, driven by a Gnome revolving motor. The aeroplane, although apparently intact and in good working order, became unmanageable, and turning completely over, fell to the ground. Now, the gyroscopic effect of the 167-pound motor running at 1,200 revolutions per minute, must have been considerable. A sudden turning of the aeroplane to the right or left by the aviator would produce a strong upward or downward gyroscopic tipping tendency in the longitudinal direction. If this tendency were aggravated by a gust of wind, it is conceivable that the aviator would be unable to control the situation sufficiently to prevent a complete upset. At the time of his fall Le Blon was flying above the bay at San Sebastian, Spain, in a high, gusty wind. Is it not possible that the joint action of the wind and the gyroscopic effect of the engine and propeller was responsible for the disaster? The tragic death of Delagrange when he was using a monoplane equipped with the same type of motor suggests that his sudden upset may have been due, in some measure, to similar causes.

## GUN RECORDS IN OUR OWN AND THE BRITISH NAVY

We are frequently asked by correspondents to give some comparative figures showing the relative excellence of the shooting in our own and other navies. We would gladly do so, but it is a fact that there is no information regarding the navies of the world more difficult to obtain than this. France and Germany, in particular, never giving to the world the results of target practice. Both the United States and Great Britain, however, do publish such figures. But even here it is often difficult to establish accurate comparisons, because the data which is made public is seldom complete, either the range or the size of the target being frequently omitted, and no statement being made as to whether target or ship or both were moving. However, we offer the following comparison, which is based upon official figures.

The Engineer of London states that the results for the past year have shown that each 12-inch and 10-inch gun has averaged 0.63 hit, each 9.2-inch gun, 1.94 hits, and each 7.5-inch gun 2.47 hits, these being the average number of hits per gun per minute for the whole navy. The 6-inch, 4.7-inch, and 4-inch guns varied from slightly over 4 hits per minute for the 6-inch to 9 hits per minute for the 4-inch.

By the courtesy of Rear Admiral Mason, Chief of the Bureau of Ordnance, we are enabled to publish the average results obtained on all the guns on all the ships taking part in target practice in the United States navy. Whether the ranges and the size of the targets corresponded to those in the British navy, we are unable to say. The results are, for the 12-inch guns, 0.72 hit per gun per minute, for the 10-inch, 0.76, for the 8-inch, 1.83, and for the 7-inch, 3.13 hits per gun per minute, while the results obtained with the 6-inch, 5-inch, 4-inch, and 3-inch were practically the same as were obtained in the British navy. One 7-inch gun holds the remarkable record of 10.26 hits per minute, while the highest score with the 12-inch gun firing when the ship was under way in smooth water, was 4 hits per gun per minute obtained on the United States ship "Ohio."

## CERTAIN ADVANTAGES OF LIQUID FUEL

To judge from a succession of articles which have been appearing in one of the newer and certainly the most noisy of the London daily papers on the use of liquid fuel in the British navy, one would suppose that the virtues of this fuel had only recently been discovered and that the Admiralty had determined to abolish its coal depots and turn the bunker rooms of its warships into oil tanks. As a matter of fact, any such sweeping substitution of oil fuel for coal is not now contemplated, nor ever will be, either in the British or any other navy. The natural sources of oil supply are not sufficient in capacity, nor are they so widely distributed, as to make it possible either for the merchant marine or the navies of the world to make a wholesale substitution of oil for coal. Some countries, notably the United States and Russia, possess such abundant supplies that they could, if they so wished, make a much more complete use of oil, and, because of this advantage, it is not unlikely that our navy at least will ultimately make a more extensive use of oil fuel than the navy of any other power.

The advantages of oil over coal are so many that were there as much oil in sight as coal, the new fuel would inevitably supersede the old altogether. In the first place, the higher evaporative value of liquid fuel not only enables a larger quantity of fuel to be carried in the same space, but its use renders possible a decrease of 75 per cent in the number of stokers or fire-room attendants. Being in the liquid form, it can be employed as ballast and pumped into remote quarters of the ship far removed from the boiler room and inaccessible for the handling and transportation of coal. For the merchant ship this means not only a saving in the fuel and labor bill, but a positive gain in cargo capacity, while for the warship there is a similar reduction of expense, and what is of far greater value, a considerable extension of the cruising radius, or the distance over which the ship can travel without replenishing her fuel supply. For the merchant ship there is the further advantage that the bunkers can be filled by a pipe line without the delay, dirt and disorder which accompany the present coaling operations, while for the warship there is the strategic advantage that the ship can take on fuel by a pipe line from a tank ship at any place and in any but heavy weather. Furthermore, the use of oil enables a whole fleet to steam without emitting those tell-tale clouds of smoke which are one of the surest means of betraying its presence to the enemy.

## ANCIENT AND MODERN IRRIGATION.

A strong sentimental interest will be aroused by the announcement that the great irrigation works, which at the very dawn of history rendered the land of Mesopotamia a garden of fertility, are now being repeated on an extensive scale under the same engineer who was responsible for the very successful irrigation works in the valley of the Nile. Our United States Consul at Bagdad, Turkey, speaking of the importance of these works, says that if the plan should succeed only in part, it promises to revolutionize commerce and shift trade balances and traffic in that part of the world. A total of 12,500,000 acres of land is to be reclaimed at an estimated cost of $18 per acre, and so fertile is the land when properly irrigated, that its estimated value, according to the Turkish government, will be $155 per acre, the soil being capable of yielding large crops of wheat, barley, and cotton.

We spoke of sentiment entering into the interest with which we regard this work, and there is certainly something that appeals strongly to the imagination in the fact that both in ancient Egypt and in even more ancient Mesopotamia, the Anglo-Saxon, after a lapse of four or five thousand years, should be repeating on a larger scale and with the greater skill rendered possible by modern appliances, those feats of irrigation which are one of the chief glories of the ancient, but never-to-be-forgotten, races that once flourished in the valleys of the Nile and the Euphrates.

Whatever may be the future fate of the great Anglo-Saxon race, the vast works of irrigation which it has carried out in India and in Egypt and is now actively prosecuting in Mesopotamia, must ever stand out as one of the brightest evidences of its civilizing and uplifting activity.

During the recent progress of President Roosevelt down the valley of the Nile, his visit to the great reservoir at Assouan and the sight of the marvelous fertility with which it has enriched the valley below, must have carried his thought to those even greater works of irrigation which are now being prosecuted in the arid region of our Western States; works which owe their inception largely to his own tireless energy and enthusiasm. Here also the latest and most powerful branch of the great Anglo-Saxon race, in the space of a few years, has completed the initial work for a project which promises to bring thirty million acres of unproductive land under the richest cultivation. And in this connection it is timely to draw attention to the great ability with which the Reclamation Service has done and is now carrying on its work. A well-deserved tribute to the engineers in charge was recently made by Senator Newland of Nevada, in which he stated that the projects had been for the most part wisely selected and the work well done, such mistakes, none of them serious, as have been made being the result of the extraordinary pressure brought to bear upon the Reclamation Service by the political representatives of the regions affected. Said the Senator: "We have had one of the most capable and honest construction services organized that has ever existed in the history of this country. The Committee on Irrigation of the Senate has been engaged during the past year in visiting these various works, and not a whisper of corruption has reached them. It has been a work conducted with rare intelligence, with rare integrity, and with rare speed."

The work already accomplished consists in the provision of dams, headworks, etc., and the $30,000,000 now required is for the purpose of utilizing the water so stored, by the construction of canals for distributing the supply upon the millions of acres which only await its arrival to spring into instant fertility.

## TESTS OF TUNGSTEN LAMPS

In a bulletin recently issued by the University of Illinois, T. H. Amrine and A. Guell present the results of an important study of various types of tungsten and incandescent lamps, a study which should prove of considerable interest in view of the growing importance of metallic filament illumination. The conclusions of their investigation may be thus summarized:

Comparisons of the durability of filaments made by the colloid, deposition, and paste processes are very difficult to make because the three types are usually mounted differently. Undoubtedly the manner of mounting the filament has a great effect upon its life, and whether the superior life of one type lamp is due to the fact that it has a better scheme of mounting or to the fact that the process of manufacturing is better, can hardly be decided definitely from these tests. Tests of filaments made by the three processes and mounted in exactly the same way would be necessary to decide the question definitely. From the tests described, however, the colloid process seems to give a filament that is less durable than the other two. The tests show that performances of tungsten lamps vary to a surprising degree, depending upon the kind of lamps used and upon the conditions under which they are burned. Some lamps will give as high an operating cost as the old carbon lamps while burning under certain conditions, whereas other lamps will give good results under those same conditions. Under the best conditions, however, the tungsten lamps now on the market give excellent results. Their efficiency is maintained in a remarkable way and the life is very long, often several times what the advertised life is. Breakages in shipment and handling have been reduced to a small fraction of what was formerly common. Of three hundred lamps purchased for the tests by the experimenters, only three were received with broken filaments; and although the lamps in some of the tests were handled dozens of times, almost no trouble was experienced so far as the breakage of filaments was concerned.

## ENGINEERING.

**The Minister** of Public Works of Panama will shortly ask for bids for the construction of a railroad from Panama to David, a distance of 200 miles. Bids will be asked also for lines from David to Bocas del Toro, and from Panama to Los Santos.

**The Navy Department** recommends an appropriation of $10,000 for prizes, etc., to be awarded ships in commission for general efficiency and economy in coal consumption It is estimated by the Department that competitions of this character have resulted, and will continue to result, in a saving of ten per cent in coal consumption

**In spite** of the steady increase in passenger travel in this city, the opening of the new East River bridges is beginning to tell heavily upon the traffic over the East River ferries. The Union Ferry Company of Brooklyn has been obliged to discharge three boat crews, and change the schedule on three different lines from a 10-minute to a 20-minute headway

**Acting on the recommendation** of the Public Service Commission, the Interborough Company of this city will install cars with destination signs on the elevated lines, which will automatically tell the name of the station the train is approaching The great convenience of this arrangement to the traveling public will be out of all proportion to the small cost of putting it in place

**The British Navy** estimates for the present year call for five battleships of the dreadnought type, five protected cruisers of 25 knots or over, twenty destroyers, a number of submarines, and two floating docks In cluding the ships to be laid down this year, the dreadnoughts built or building for the three leading naval powers are for Great Britain, 27, Germany, 17, United States, 10

**Speaking** on the subject of defective open-hearth rails, at the last annual convention of the American Society for Testing Materials Robert Job emphasizes the fact that the mere term 'open hearth is in itself no guarantee that the rails made under that system will give good service, since they are subject to the same general defects of manufacture as Bessemer rails, and hence require equal care during rolling etc

**The Pennsylvania Railroad** recently ran its first Pullman train from Harrison, N J, by way of its new tunnel system to Long Island and return It will be three or four months, however, before the whole system is thrown open for public service The tunnels to Long Island, unless the plans of the company miscarry will be publicly opened on the 15th of May, and those to the westward under the Hudson River by about the 15th of July

**The Army Board** is making some important experiments to determine the resisting power of a solid mass of concrete, as compared with armor plate In a recent test with a 12-inch gun, a shot was fired which penetrated the concrete for a distance of 21 feet, which is equivalent to the piercing of a 19-inch armor plate The target is now being reconstructed for tests with the new 14-inch gun, which it is expected will give even better results.

**The Director** of the Royal Dockyard at Castellamare, Italy, has produced, if the reports are to be believed, a torpedo boat without funnels By means of electrical ventilators the products of combustion are discharged from the vessel without the assistance of smokestacks. The first experiments, on a trip from Castellamare to Naples, are said to have been extremely successful, no smoke being shown and the vessel getting up steam with great rapidity

**The shortage** or surplusage of freight cars is one of the reliable indications of business activity, if not of business prosperity The great surplus of cars which existed at the time of the panic in November, 1907, was gradually reduced until it was wiped out in the autumn of 1909 To-day, not only is there no surplus, but the indications are that during the coming season there will be a large shortage, due to the steadily increasing volume of business.

**The Hudson** and Manhattan Railroad Company has built two steel cars which are specially designed for transporting baggage between the steam railway terminals, which are served by the Hudson River tunnels. With a view to avoiding extra handling and trucking, each car is arranged to receive eight loaded baggage trucks, which are loaded and unloaded between platform and car over folding steel plate aprons, which form part of the permanent attachments of the car.

**The Isthmian** Canal Commission has called for the manufacture, delivery, and erection of about 58,000 tons of steel parts, which will be used in the construction of the forty-six mitering lock gates of two leaves each on the Panama Canal. These are the largest lock gates ever built. They are all about 65 feet wide, and vary from 47 feet 4 inches to 82 feet in height. Piled one above the other on end they would make a tower 1 1/5 miles in height. The contract will be worth about $6,000,000.

## ELECTRICITY

**At Harvard** University a wireless telegraph club has been formed with a view to studying wireless telegraphy, and one of the special objects is to discover some method of overcoming amateur interference

**Some time ago** the United States Steel Corporation installed two Heroult furnaces, one at Worcester Mass, and the other at South Chicago These furnaces have been in constant service ever since, doing twelve heats per day It requires between an hour and an hour and a half to refine a metric ton of steel and 190 kilowatt hours are consumed to desulphurize and dephosphorize the metal The cost of repairs on the furnace has amounted to about six cents per ton of steel, and the electrodes are consumed at the rate of six pounds per ton.

**A test** of the telephone service in Wisconsin was recently made by a commission. The investigation was carried on secretly, so as to determine the actual conditions of service It was found that the average time between a call and a response was 4 78 seconds The quickest average response came in 3 17 seconds and the slowest in 7 3 seconds Those exchanges which most quickly responded to a call were found to be more efficient in every other respect as well, so that this single test provided a gage of the service offered by the exchanges

**It is** remarkable that while wireless telegraphy has made rapid strides very important considerations have been almost entirely neglected Much attention has been paid to attunement and selectivity and also to the refinement of instruments while the development of the antenna has been slow At the receiving station particularly not much has been done toward locating the antenna wires so as to intercept a maximum of wave energy Aside from Braun's fan shaped grid which marked an epoch very little along this line has been extensively adopted in practice

**A telephone** cable loaded with Pupin coils was laid in Lake Constance in 1906 This was a lead-covered cable and it was very difficult to lay it on account of its great weight Mr Dieselhorst, who laid the cable has been experimenting with loaded submarine telephone cables and has evolved a construction which is to be used across the English Channel to connect London with Paris The cable is covered with gutta percha and wire sheathing and the loading coils have been introduced so ingeniously as to increase the diameter of the cable from one inch to but three inches So gradually is the cable swelled at the loading points, that it can be paid out over a four foot sheave wheel The cable has been tested in salt water for fifteen months, and from time to time has been subjected to pressures of four tons per square inch

**A series** of tests has recently been made to determine the strength of the metallic filaments of lamps and their resistance to shock The lamps were tested by placing them at the bottom of an inclined plane, and rolling rubber balls filled with lead down the plane The shock was varied by starting the balls at different distances from the lamps It was found that with lamps of equal voltage the strength of the filament varied inversely as the candle-power and for lamps of equal candle-power the strength varied inversely as the voltage In some lamps it was found that certain parts were more sensitive to shock than the filaments. When the filaments were heated to a white heat they became too flexible to be broken by a shock, but the loops were distorted under repeated blows until they came in contact with each other

**Sterilization of white wine** is the object of a paper presented to the Académie des Sciences by Messrs. Maurain and Warcollier Previously they studied the action of ultra violet rays from a quartz mercury vapor lamp upon cider in fermentation With the same apparatus they made researches upon sparkling white wine and found how much time it took for the rays to act upon different thicknesses of layer so as to destroy the fermenting principle and thus prevent any new fermentation Using layers of wine of ¼ millimeter (0 01 inch) held between a 0 2 inch quartz plate and a glass plate and exposed to the lamp so that this latter was 1 6 inches distant, they found that fermentation was stopped in all cases for an exposure of above 10 seconds and never for an exposure below 5 seconds. With 1 7 millimeters (0 07 inch) exposed at the same distance from the lamp fermentation was always stopped after an exposure of over 1 minute and never in less than 30 seconds. It is to be noted that in the case of pure cider, to sterilize it we need an exposure of over 2 or 3 minutes for the first mentioned thickness of layer, and sterilization is not reached even after 15 minutes exposure for a 0 04 inch layer Thus it will be seen that the sterilizing of white wine can be more easily carried out than that of cider, this being no doubt due to the fact that the wine is more transparent to ultra-violet rays.

## SCIENCE.

**Prof. Hilprecht's** tablet, said to uphold the Biblical account of the Deluge, was discussed at a meeting of the American Oriental Society at the Johns Hopkins University Prof. G A. Barton of Bryn Mawr College, Prof Paul Haupt of Johns Hopkins University, and Prof Albert T Clay of Yale University, thought that Prof Hilprecht had been too imaginative in interpreting the fragmentary inscription It is asserted that the restoration made by Prof Hilprecht in filling in broken lines were conjectural emendations Prof Hilprecht's claim that the tablet was written some time between 2137 and 2005 B C is regarded as unfounded, it being stated that the tablet belongs to a much later period

**The perfume** and flavor of vanilla are due to a substance called vanillin, which also occurs as an ingredient of numerous resins Vanillin has been made synthetically by Tiemann and Haarmann from coniferin a glucoside which is found in various species of conifers The same chemists subsequently made the commercial synthesis of vanillin possible by substituting eugenol for coniferin The price of vanillin has fallen from $770 per pound in 1876 to $4 per pound in 1909 A further reduction is scarcely possible because of the high price of eugenol Hence chemists have been experimenting in another direction and Guyot and Gry have applied to the preparation of vanillin the general methods of synthesis of aromatic aldehydes, which were recently discovered by Guyot Their experiments are described in a recent number of the Bulletin de la Société d Encouragement

**The price** of pure Para India rubber, which in 1903 was 88 cents per pound, rose last year to $2 25 per pound This increase in price gives additional interest to the processes of regeneration of waste rubber and of the manufacture of substitutes The regeneration of vulcanized India rubber consists in removing the sulphur, which was added in the process of vulcanization The scrap rubber is assorted according to quality and is treated either with sulphuric acid or with potash, for the purpose of destroying fibers of cloth, etc and of removing the greater part of the sulphur The material is then ground and washed This regenerated India rubber is used only as an addition in small proportions to new rubber Artificial or imitation rubber is made by methods which resemble the process of vulcanizing natural India rubber, for example by treating linseed oil with sulphur or sulphur chloride

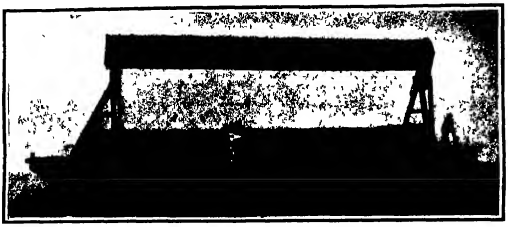
**One of the most** interesting results of the Smithsonian African Expedition has just been published by Mr Gerrit S Miller Jr curator of the Division of Mammals U S National Museum under the title of Description of a New Species of Hippopotamus. There have been for some years in the collections of the National Museum two skulls of hippopotami, one of which was from the Zambesi River East Africa and the other from Angola West Africa These skulls differed materially in several details of form chiefly however in the constricted shape of the rostrum but the characters were not deemed of sufficient value to justify the creation of a new species for the differences might have been due to individual variations The receipt of eight skulls from British East Africa collected by the Smithsonian African Expedition showed conclusively that the individual variations were so slight in the East African specimens that Mr Miller was led to believe that the two skulls represented two distinct species one from East Africa and one from West Africa A critical study of the skulls revealed other differences in their characters that were of sufficient importance to justify Mr Miller in making a new species of the West African specimen to which he gives the name *constrictus*

**The gas bags** of modern balloons are made of a cotton fabric coated with India rubber in the most careful manner, in order to assure perfect impermeability without sacrificing lightness For all large balloons, and especially for dirigibles two layers of cloth are superposed and cemented together The outer skin is covered with India rubber on one side only but the inner skin is coated on both sides In German balloons the inner canvas is cut straight and the outer canvas is cut bias In this construction gores with angles of 45 deg are used and the seams are covered which causes a slight increase in weight French balloon makers prefer to cut both canvases straight Experiments show that the tensile strength of the envelopes thus made is approximately equal in all directions Each method of construction has its advantages and its defects As India rubber, even when vulcanized, is altered by exposure to light, the canvas is colored yellow in order to arrest the violet and ultra-violet rays, which are the most active The pigment used in France is chromate of lead, which unfortunately must be applied to the canvas before it is coated with rubber, and which consequently prevents the vulcanization of the rubber, because the chromate of lead is blackened by heat. Picric acid is free from this objection, but its employment is too dangerous.

## THE "VIKING"—SELF-DUMPING DECK SCOW.

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

A novel system of self-dumping scow especially designed for the discharge of rock and solid débris has been devised by Mr A F Viking engineer and shipbuilder of Stockholm At this port the economical dumping of such material into the water is of particular interest inasmuch as the blasting of rock in connection with the extensions to the harbor or the streets of the city is in continuous progress Several designs for automatic dumping have been evolved but the "Viking" system so called after its designer, has been the first to be submitted to practical test and has proved remarkably successful Through the courtesy of the inventor we are enabled to illustrate and describe this new barge It differs in its action from any other vessels of this class in service inasmuch as instead of the contents being dumped through self-opening doors in the bottom of the hull the scow is tipped over on its beam ends by a very simple action The load is carried on a flush deck or the latter is fitted with low bulwarks On one side, extending the full length of the scow is an elevated cylindrical tank $D$, mounted about 16 feet above the level of the deck on two tripods When it is desired to dump the barge, the equilibrium of the latter is upset merely by forcing water through the agency of compressed air into the elevated tank, which causes the scow to tilt over and shoot its load Should the flush deck be fitted with low bulwarks, these are fashioned in the form of bottom hinged doors on the discharging side, so that they fall down as the barge heels over, and permit the load to be shot cleanly



After dumping, the scow returns to an even keel.

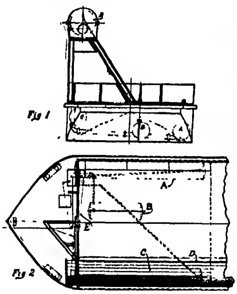
In the hold of the scow on the side opposite the elevated cylindrical tank is carried another tubular tank $A$ about half the length of the former This is filled with water, and in the case of the scow illustrated holds about six tons for a load of 200 tons on the deck Alongside this water tank is a small cylindrical vessel $B$ containing compressed air the pressure being approximately seven atmospheres On the same side as the elevated tank in the hold below, is a third cylinder $C$ also about half the length of the elevated cylinder which at first is empty, but which is always open to the outer atmosphere through a small pipe

The water vessel $A$ in the body of the pontoon is in open communication by means of a pipe $E$ with the elevated tank, and the former is also in connection by another pipe with a valve box placed at the foot of the tripod carrying the upper tank When the valve in this box is in its initial position, this second communicating pipe is open to the free atmosphere The compressed-air vessel is also connected to this valve box, but is shut off from the same until ready for dumping. The third vessel below the elevated cylinder, as already mentioned, is always open to the free atmosphere through a pipe, but there is a second pipe and valve provided in connection with the main communicating pipe between the first water tank and the elevated cylinder It will thus be seen that there is always open communication between the first water tank and the elevated cylinder by means of a main pipe which is carried up alongside the vertical leg of the tripod at one end In addition there is a smaller air pipe running up one of the triangular legs and passing right into the body of the tank, having its outlet near the top of the cylinder inside. This pipe is in connection with the outer atmosphere, so that normally the upper vessel is full of air

The load is stowed on deck in the manner shown in the illustration. When rock is handled, bulwarks on three sides only are necessary, the fourth side from which dumping is effected, below the elevated tank, being left quite open or at the most having only a low ridge If soft material is carried, hinged doors, as already described, may be used, these automatically opening under the pressure from the load on deck when the scow is inclined in the dumping operation, and falling flat and clear so as not to obstruct the shoot

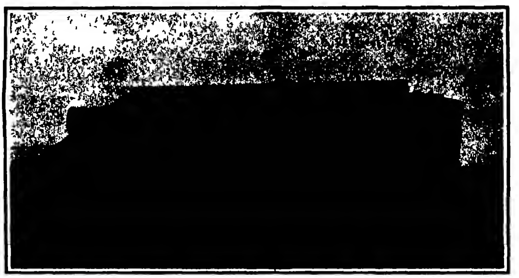
When the loaded barge has been towed to the dumping site, a cord is pulled connecting the mechanism of the scow with the tug This opens a valve, which permits the compressed air to flow to the valve box, and also a slide valve in the latter, whereby the compressed air is admitted into the lower water vessel $A$. The pressure exerted forces the water from the lower tank into the elevated cylinder $D$, the displaced air in the latter escaping, and, as the upper tank becomes charged, the barge loses its equilibrium, heels over on the elevated tank side, and the load slips off the inclined deck into the water When the load is shot the control cord is again pulled, the slide valve in the valve box is returned to its normal position, cutting off the supply of compressed air to the lower water tank, and at the same time opening the latter to the free air

The load may slip off the deck at varying inclinations, this factor depending on the friction between the load and the deck and the character of the débris If the slipping takes place early, at a low deck inclination, the upper cylinder may never reach the water, for the scow rights itself immediately the load is discharged. Should such result, the water forced into the elevated tank returns to the lower water tank directly the compressed-air supply to the latter is cut off by the second pull of the cord controlling the mechanism It may happen, however, that the scow heels right over, and the upper tank is brought into the water, the barge thus floating in an inclined position. To bring it back to the upright position a third pull is given to the control rope, which at once opens the communication between the upper tank $D$ and the water vessel $C$ placed immediately below it in the hold As this latter tank is always placed in a position lower than the elevated cylinder, the water must flow by gravitation into it. When a sufficient quantity of water has passed from the upper to the lower cylinder, the barge rights itself, and the water remaining in the elevated tank as well as that in the tank immediately below, returns to the main water cylinder on the opposite side of the vessel in the hold, by gravitation This accomplished, a fourth pull on the control cord returns all parts to their original positions. The compressed air is fed into its vessel by means of a hose coupled to a valve in the top of the air chest, and when sufficiently charged the valve is closed and the hose removed. When the barge is in its upright position, all water in

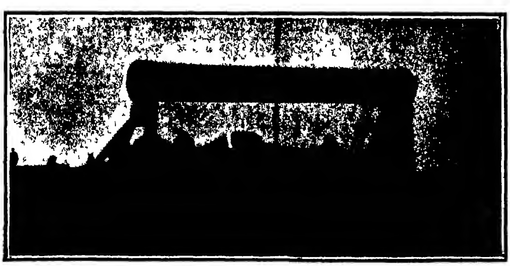


$A$, $B$, $C$, $D$ are ballast tanks by the emptying and filling of which the scow is dumped and righted

End elevation and half-deck plan of scow.



The scow tilted and load sliding into the water



Loaded and ready for dumping.

THE "VIKING"—A SELF-DUMPING DECK SCOW.

the elevated tank, or the one immediately below it, must return to the first tank on the opposite side of the barge, as this latter is placed at the lowest point, the return being purely gravitational It will also be seen that the water circulating between the tanks cannot escape. Glycerine is mixed with the water to prevent freezing in cold weather, so that the system can be used any time of the year irrespective of climatic conditions.

The scow shown in the accompanying illustrations is in daily service at Stockholm, and has proved eminently satisfactory to the engineers of the city The results that have been obtained prove that this self dumping barge is superior to the ordinary hopper type with false bottoms. It is cheaper in first cost and maintenance, can handle rock of practically any size and weight within its total capacity, and is a first class craft for any harbor transport. If desired, the elevated cylinder can be unshipped in a couple of hours and the barge used as an ordinary lighter The system is applicable to any type of barge whether of the blunt-ended type or one of fine lines It is only necessary to insure a sufficient breadth to counteract the influence from high winds The success of the flush-deck type has induced the inventor to extend the idea to craft with sunken holds for handling gravel, mud, and other semi liquid or soft material, which cannot be accommodated on a flush deck.

## HALLEY'S COMET AT ITS BRIGHTEST

BY HENRY NORRIS RUSSELL, PH D, PROFESSOR OF ASTRONOMY AT PRINCETON UNIVERSITY

It may have seemed remarkable to many people that so long a time has elapsed since the first observation of Halley's comet at its present return, and yet it has not shown itself at all to ordinary eyes. The accompanying illustration (Fig 1) will help to explain this. When first detected last September with very powerful telescopic aid it was far beyond the limits of our diagram, at twice the distance of Mars from the sun, and nearly as remote from the earth At first the two

Fig 4 Spectrum of Halley's comet

Photographed at the Yerkes Observatory by Prof Frost, January 14th 1910 The spectrum of the comet is in the middle between the two brightest star-spectra. See description in text. The blue end of the spectrum is on the right, the ultra-violet on the left.

bodies approached each other rapidly, but before the end of the year our planet crossed the line joining the comet with the sun, and by January 1st, as the figure shows, we were moving almost straight away from it During the early part of the year the earth and comet passed on opposite sides of the sun, so that it was lost to our view early in March

About the time that this is printed it will come into sight again, on the other side of the sun rising before daybreak But now its path has curved so that it is coming toward us—almost directly, if we take our motion into account as well as its own It therefore seems to stand almost still among the stars, while growing steadily larger and brighter, so that any one might tell by its mere changes in appearance that it was approaching us rapidly

Finally, about the middle of May the comet will apparently approach the sun again, and on the 18th it will pass in front of him, literally between us and the sun, transiting the latter's disk If at this time its tail is more than fifteen million miles in length we will pass through it, as the figure shows.*

The comet's closest approach to us comes two days later, on May 20th, when it is but fourteen million miles away For a few days following this it will be splendidly visible in the evening sky, and then it will fade gradually as it recedes from us.

It is clear from the diagram that this apparition of the comet is an exceptionally favorable one, for it passes the earth almost at the point where their orbits come nearest to one another If it had returned only three weeks earlier, it would have come as near as possible—only seven millions of miles—but at this time it would have been directly south of the earth, astronomically speaking, almost over our south pole, and quite invisible from northern latitudes. It therefore appears that the present conditions are almost ideally favorable for observers placed as we are, north of the equator

The illustration on the first page shows better than any verbal description where to look for the comet in the morning sky in New York The moon and Venus

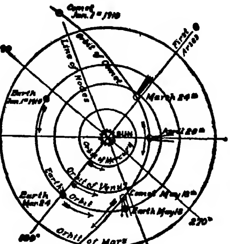


Fig 1 —RELATIVE POSITIONS OF HALLEY'S COMET, THE EARTH, AND THE SUN

are shown in the positions which they will occupy about May 1st, when, on the whole, the comet can be seen to the best advantage At an earlier date, Venus was higher in the sky, compared with the comet. There was less trouble then from moonlight, but the comet did not rise so early—about 4 A M on April 15th as against 3 A M, on the later date

The comet's brightness when it appears in the evening sky about May 20th will be sufficient to render any finding diagram unnecessary It will only be needful to look toward the west half an hour or more before the comet sets which it does at 8 20 P M on the 20th 9 15 on the 21st, and 9 55 on the 22nd, after which it will be clearly visible until after 10 P M

Our other illustrations which appear here through the courtesy of Profs Frost and Barnard of the Yerkes Observatory show the appearance and character of the comet earlier in its apparition Fig 2 illustrates its extreme faintness at the time of its rediscovery (which was announced by Prof Wolf of Heidelberg less than a week before the earliest of the four photographs here shown was taken) while it was still 400 million miles distant, both from the earth and from the sun On any one plate it is difficult, if not impossible to distinguish the comet from the multitude of faint stars around it, but on comparing the four (which show exactly the same region of the sky) it is easy to see that the stars are the same in all, while the comet is 'here to-day and gone to-morrow"

With the great Yerkes telescope (which gives far smaller and sharper images of the stars than can be reproduced on any known photographic plate) the comet was even at this time quite different from the stars in appearance, in Prof Barnard's words, "a fleck of light surrounded by a faint nebulosity" with no definite boundary His measures, made on several nights, show that its actual diameter was about 12,500 miles.

Fig. 2.—Halley's comet at its reappearance in 1909.

From photographs taken by Mr Lee with the two-foot reflector of the Yerkes Observatory These four photographs represent the same portion of the sky. The arrows point to the comet which appears like a faint star but moves from night to night.

Our second illustration, from a photograph taken when the comet was 143 million miles from the sun, and 162 million from us, shows it already well advanced in the changes which invariably accompany the approach of any considerable comet to its perihelion The head of the comet has become larger—not merely in apparent size, owing to its approach to us but actually in miles, while a faint slender tail, pointed away from the sun, makes its appearance

As Fig. 1 shows, the tail, which extends directly away from the sun, was at this time also nearly in line behind the head as seen from the earth so that its actual length must have been much greater than it appears to be—about five million miles, according to Prof Barnard

This considerable development of the tail, while the comet was still at two and one-half times its least distance from the sun, makes it probable that at and after the perihelion passage, on April 20th it will be much longer, probably long enough to envelop the earth as it sweeps past.

Our third illustration shows the spectrum of the comet photographed on January 14th, when it was about 170 million miles from the sun

In taking such a photograph, a prism is placed in front of the camera. The light of a star is thus drawn out into a line which, by letting it trail on the plate is broadened into a band, crossed by the dark lines which tell us what absorbing gases exist in the star's atmosphere Most of the objects on the plate are the spectra of stars near the comet obtained in this way The comet's spectrum is near the middle between the two very broad and conspicuous 'comparison spectra, which were produced by supplementary exposures on some bright star, and serve as reference marks to find the position of the lines in the spectrum of the comet itself The latter unlike that of the stars consists

Fig. 3.—Halley's comet on February 3rd, 1910.

From a photograph taken at the Yerkes Observatory by Prof Barnard. As the instrument was kept pointed at the comet during the exposure the stars appear as short streaks. The actual length of the comet's tail is about five million miles

mainly of bright bands or lines three of which are conspicuous The brightest of these as is shown by comparison with the hydrogen lines of the comparison spectrum is the so-called cyanogen band at the extreme violet end of the visual spectrum The others are probably as in the case of other comets, also due to gaseous compounds of carbon

Between these bright bands can be seen a faint continuous spectrum, due to reflected sunlight

When the comet first appeared the photographs made at the Lick Observatory showed this continuous spectrum alone At that time it must have been shining entirely by reflected light, but by the date of our illustration it had already begun to be self luminous This is corroborated by the fact that its brightness increased much more rapidly than could be explained by the mere increase in the amount of reflected light, due to its approach to the sun and to us

This intrinsic light of the comet, as its spectrum shows, is given off by luminous gas, but we do not yet know what makes this gas shine It can hardly be high temperature, for the comet had just come from the depths of interplanetary space, and did not yet receive nearly as much heat from the sun as the earth does. It must however, be due to some kind of solar action, for it increases very rapidly as a comet approaches the sun We can reproduce the same spectrum in the laboratory by passing an electrical discharge through a vacuum tube containing compounds of carbon and nitrogen at very low pressure

It is of special interest that, even if the carbon compounds form but a small percentage of the gas in the tube, their spectrum becomes relatively prominent when the pressure is made very small say 1/100 000 of that of ordinary air It may be, therefore, that at the lowest pressures carbon compounds have an exceptional capacity for shining, and it would be unsafe to conclude that they are the principal gaseous con-

* Prof. Barnard has informed us that the tail was 14,000,000 miles long on February 27th, from which it may well be inferred that it is much longer than 15,000,000 miles now.—Ed.

stituents of the comet, because they give off almost all the light

It may be added that the cyanogen bands in the spectrum are produced not only by the poisonous gas of that name but in all cases when carbon and nitrogen are together under electrical excitement For example they are very strong in the spectrum of an ordinary arc light where the nitrogen comes from the air and the carbon from the terminals It would be about as reasonable to conclude that an arc light was poisonous after looking at it through a spectroscope from a distance, as to make the same deduction about a comet

Whatever may be the origin of this intrinsic light of comets it is responsible for most of the phenomena which make them of general interest for almost all the light of the tail as well as of the head of a bright comet is of this kind If Halley's comet shone by reflected sunlight alone it would be barely visible to the naked eye, even under the most favorable circumstances.

Actually owing to its intrinsic light it has been a conspicuous object at every return for the last 2,000 years The only gap in the record—in A D 912—has lately been filled by the discovery of unmistakable references in old Japanese chronicles.

The actual quantity of matter composing it must however be very small as compared with the more familiar heavenly bodies It is possible to form a rough guess as to its amount by considering the amount of light which it reflects when it is not shining on its own account From the estimates of magnitude made last September, it appears that a single body only a little over 30 miles in diameter at the distance of the comet would have sent us as much reflected light provided that its reflecting power was equal to that of the moon, which is lower than that of most of the planets

It is, therefore clear that the comet must be composed of separate particles widely separated The whole cross-section of the comet (112,600 miles in diameter) is about 120 million square miles, while the total area of all the reflecting particles, according to the above estimate is about 1 000 square miles A ray of sunlight falling on it has therefore less than one chance in 100,000 of being stopped, and all the rest of getting through some empty space It is no wonder that comets are transparent, and that stars can be seen through them! If we only knew how big these particles were, we could now estimate their number and their total mass But here we are quite in the dark As the light of the comet seems uniformly diffused and it shows no signs of resolution into points of light, the number of particles composing it must at least be counted by thousands Their average diameter must therefore be less than a mile, though they may vary enormously in size If all gathered into one compact group they could at most hardly exceed in bulk the satellites of Mars or the smallest of the asteroids

But how much smaller than this limit their actual dimensions may be we do not know If, purely for illustration, we suppose that they average an inch across, there would be some five or six million millions of them This sounds like an enormous number, but if we calculate the bulk of the comet we find that there would be only five or six particles per cubic mile of space on the average inside it Near the center they would doubtless be more closely packed, and more thinly toward the outer parts of the comet. The combined bulk of all these particles would be about 80 million cubic yards a large amount from the engineering standpoint but not equal to the quantity of water which falls within the limits of the smallest State in the Union during a heavy rainstorm

This may serve to give us some idea of the extreme tenuity of the comet as a whole If we took a space as big as the comet, that is, half as much again in diameter as the earth, and sowed ordinary golf balls through it at the rate of two or three per cubic mile, leaving the intervening space absolutely vacant we would get something that would look quite as bright as Halley's comet - if put alongside it when it first appeared

The gaseous matter which gives most of the light at perihelion probably oozes out of the solid particles as these grow warm under the sun's heat when they approach it As the gas becomes luminous under solar action, the brightness of the comet increases and its outer regions originally invisible because the number of reflecting particles was too small to influence our eyes, gradually come into view

Some of this is repelled from the head of the comet, by little known forces, and driven away from the sun by the action of the sunlight which, as is well known, exerts a force of repulsion which, if a particle is exceedingly small as are the gaseous molecules, is stronger than the attraction of the sun

Thus arises the long and magnificent tail which, like the smoke-trail of a steamer at sea is ever being renewed at one end and fading away at the other, even though it seems to accompany the comet in its journey

As the comet recedes from the sun, much of this gaseous matter has thus been lost, never to be regained Some of the remainder probably condenses round the solid particles when they become cold, and some escapes into space

The comet is thus gradually losing its substance, and in the course of ages it may be deprived of all its tail forming material, and lose its former glory This seems to have actually happened to some of the short period comets, one at least of which has disappeared altogether

Halley's comet is perhaps preserved from such a fate by the longer interval between its returns to the region near the sun, where its activity takes place It may be, too, that it has more of the right sort of material to spare for a tail But the time may come when most of this is lost, and its successive appearances may gradually lose those impressive features which have so long inspired awe and wonder in the hearts of mankind, and dwindle at last into something which the professional astronomer alone will be interested in watching

**The Mercury Vapor Lamp and Its Effect on the Eye.**

About a year ago we published a reference to a report of Prof J Norman Collie, F R S, stating in effect that a German medical journal had described certain cases of alleged injury inflicted upon the eyes by rays of mercury vapor lamps These cases referred to all prove to have resulted not from the mercury vapor illuminating lamp, which is now so largely in use in this country and which is constructed with a tube or container of glass, but from a special lamp used in medical, sterilization, and chemical processes, having a quartz container The medical or sterilizing lamp, to be sure, uses mercury vapor, but its container being of quartz, it is transparent to those rays which may be injurious to the eyes, while glass is opaque to such rays and does not permit their passage The quartz lamps referred to by Prof Collie are intentionally made to omit germ-destroying rays Dr Charles P Steinmetz who has made a careful study of mercury vapor lamps used for illuminating purposes, stated in an article in the Electrical World and Engineer of February 21st, 1903, as follows

"The mercury arc therefore is the only known artificial illuminant which is perfectly harmless and thus especially suited for use where accurate work has to be done by artificial illumination, as in drawing rooms, offices, factories, etc"

The same scientist in an article in the Daily Union, Schenectady N Y, on January 17th, 1903, stated as follows

"Therefore electric lights are less harmful than gas or oil lamps, being whiter, and the white daylight the least harmful while the mercury arc light which is entirely devoid of red rays, is absolutely harmless, and a person can look straight into one of these mercury arcs of enormous brilliancy without being blinded by it"

In one of Dr Steinmetz's books entitled "Radiation, Light, and Illumination" he makes the following statement

"The harmful effect of working very much under artificial illumination is largely due to its energy effect, incident to a large amount of orange, red, and especially ultra red in the radiation of incandescent bodies used for illuminants and thus does not exist with 'cold light, as the light of the mercury lamp"

**The Current Supplement.**

Prof R F Ruttan writes most interestingly in current SUPPLEMENT No 1789 on the manufacture of alcohol from sawdust and other wood waste. A novel type of automatic stamp-vending machine is described and illustrated Prof Charles Edward Lucke writes on the development of power systems. Prof Otto N Witt's paper on fast and fugitive dyes is concluded Harlan I Smith presents some curious information on the wooden monuments of the Northwest Coast Indians A biography of the famous Dmitri Ivanovitsch Mendeléeff is published A method of instantaneous microphotography is described

**Official Meteorological Summary, New York, N. Y., March, 1910.**

Atmospheric pressure Highest, 30 51, lowest, 29 47, mean, 30 8. **The Highest Dam.**

At the hour of two in the morning of Sunday, January 16th, the completion of the Shoshone dam in Wyoming was announced. This is the highest dam in the world, being 328 4 feet from the base to the parapet. It is located in the profound canyon of the Shoshone River, in one of the wildest and most picturesque regions of northern Wyoming The walls of the gorge are nearly perpendicular, and rise nearly 2,000 feet above the stream At its base the dam is 70 feet across; on top it is 175 feet in length, and at the base the dam is 108 feet wide

The completion of this dam creates an enormous reservoir, having a surface area of ten square miles and an average depth of seventy feet The capacity of this irrigation basin in gallons is something like 148,588,512,000 The construction of this great dam was attended with difficulty from the beginning, owing partly to the inaccessible section in which it stands.

The dam is to control for all time the great floods of the Shoshone River and to provide an ample water supply for the irrigation of more than 100,000 acres of exceptionally fertile land in the valley below, a portion of which is now available for settlers under the terms of the reclamation act.

The contract for the Shoshone dam was let September 18th, 1905, to a Chicago firm for $515,730 This firm, however defaulted, and the work was completed by another contractor

**Rail-Cleaning Car.**

When streets are cleaned by sweepers, whose brushes push the dirt before them, the dirt is swept into the grooves of the street railroad rails and then compacted by the wheels of the running cars The rails so coated with dirt offer a greater resistance to the electric current, thereby causing a greater amount of power to be used for the propelling of the cars. The rails must be constantly cleaned to avoid loss of current.

The Hanover Street Railway Company has built for this purpose a special rail-cleaning car It is similar in construction to a regular two-axle car, and has two 25-horse-power motors Between the front and rear wheels on both sides of the car are steel brushes, which loosen the dirt from the rails This dirt is automatically removed by a vacuum pump, and deposited in a box built into the lower part of the car between the axles of the driving wheels The vacuum pump is operated by an electric motor attached to the dirt box. To avoid the raising of dust in dry weather, a sprinkler and two tanks, holding about 925 gallons of water each, are provided

As soon as the box is filled, an automatic alarm notifies the motorman who shuts off the pump, raises the brushes, and takes the car to a place where it can be emptied and made ready for another trip

This car can be run at any rate of speed allowable in street traffic up to 17½ miles per hour, and still will work with good results It can be run by one man and the amount of power used at a speed of 10 miles per hour is only about 3,000 volts per mile. The car can clean daily an average of 45 miles of track, using according to weather conditions, up to 132 gallons of water and taking up to one cubic yard of dirt per mile of track

**Death of Thomas A. Baxendale.**

The founder of the box toe industry in this country, Mr Thomas A Baxendale, died at Brockton, Mass., on April 1st at the age of seventy A native of England, Mr Baxendale came to Brockton in 1867 a poor man. The shoe industry was then in its infancy He entered one of the large factories and invented the box toe which is now used in nine-tenths of the shoes that are worn Later, with John Simmons as a partner, he founded the firm of T A. Baxendale & Company He invented many machines for producing shoes, most of which are now in common use. He died a wealthy man

**Death of Thomas B. Jeffery.**

Mr Thomas B Jeffery, who invented what is known as the clincher pneumatic tire, died on April 3rd, at Pompeii, Italy He was for more than twenty-five years a partner of the firm of Gormully & Jeffery, makers of bicycles. English by birth, he came to this country at the age of eighteen, and settled in Chicago. He took an active interest not only in the development of the bicycle, but in the automobile as well.

**Death of Paul Theodore Sievert.**

Paul Theodore Sievert died January 11th, 1910, in Dresden. He was a well-known German manufacturer and inventor He is best known for an invention in which he applied compressed air for blowing vessels of glass of any desired size.

### WANTED—A RICE HULLING MACHINE

To the Editor of the SCIENTIFIC AMERICAN:

Whoever will invent a machine to hull rice, will be as great a benefactor to the rice farmer and the consumer as Eli Whitney in the invention of the cotton gin. The farmer often gets 75 cents per hundred or less for his raw product, and generally has his crop in the mill for months before he gets this. The mills are huge structures because of the necessity for large storage, but the real mill part of the plant is about the same in machinery as a flour mill. The main processes are two, the removal of the hull and the removal of the polish. The former is accomplished by burr stones, but the grain passing from under these is not completely clear of the hull. The next process is accomplished by a cylinder of wire cloth containing a revolving core of sheepskin with the wool on, which takes off the remaining hull and the outside of the grain as well. The native French of Louisiana prepare their rice by means of a wooden pestle, which removes the hulls and leaves the polish, the most nutritious part of the grain. Usually the mills have an arrangement for coating each grain with paraffin, but this is not even an improvement except in appearance.

Whoever will invent a small machine, say in size similar to a farmer's fan mill, that will remove the hull from the grain, will remove the rice crop from the enormous toll now paid the miller, and give a cheap and healthy food to the people as a superior substitute for the present rapidly ascending foodstuffs to which we have been accustomed. There are large investments in the milling of the crop but it ought to be a paying investment with $9.75 profit between the planter and the consumer on each 75 cents received by the farmer.

C. W. CAMPBELL.

Johnston City, Ill.

### THE EFFECT OF REFRACTION ON THE TRIANGULATION OF MOUNTAIN SUMMITS

A REPLY TO MISS PECK'S STATEMENTS IN THE PRESS

To the Editor of the SCIENTIFIC AMERICAN:

Since the announcement by Mrs. F. Bullock Workman of the results of the recent scientific and carefully executed measurement of the two summits of Mount Huascaran by the professional engineers sent out to Peru by her from Paris, Miss A. Peck has favored the press with communications, the evident purpose of which is to bolster up her assertions not based on any measurement data as to the height of that mountain by attempting to discredit the figures obtained by triangulation, the most accurate method of measuring altitude known. To effect this the communications contain a quotation and two statements, one of the latter absurd and self-contradictory in its terms, so brought together as to tend to befog the mind of the reader and lead him to infer that in general the results of triangulation of a mountain summit by an expert engineer are likely to be vitiated to an extent of 4,000 feet by refraction.

The quotation from Mr. Mumm and the statement attributed to Dr. Collie, the one a publisher and the other a chemist by profession, neither of whom, so far as I know, has ever claimed to be an expert in altitude measurements, merely repeat in general terms what is well known to engineers, that no method of determining the exact amount of refraction having been yet discovered, the present heights of certain high mountains obtained by triangulation may be somewhat changed, either higher or lower, should such method be discovered in the future. Such change would probably not be great in any case, and in many cases would be very slight, varying from nothing to a few feet, for no coefficient of refraction that is likely to be used would greatly alter the results now obtained.

Between the recognition of the fact that figures obtained by triangulation may not now be absolutely, though they are essentially, accurate, and the ridiculous statement asserted by Miss Peck to have been made by a nameless friend of a so-called "former member of the British Royal Engineers" that he triangulated the great peak K-2 and obtained a height 4,000 feet greater than that now assigned to it by the Indian Survey, which impossible difference Miss Peck would have the public believe is due to refraction, there is an impassable gulf.

The possible discovery of an absolutely accurate method of determining refraction would affect chiefly the present altitudes assigned to certain very high Himalayan peaks, such as Mount Everest, which were triangulated from very distant points low down in the Indian plain, and to a less degree some other high peaks also measured from distant stations. At the discussion of a paper on mountain exploration read by me before the Royal Geographical Society in London in November, 1907, Sir Thomas Holdich, one of the most eminent living English engineers, for many years [illegible] of the Survey of India engaged in Himalayan surveying, speaking of the very highest mountains said: "We do not know exactly, and at present there is no means of determining, what the exact effect of refraction may be in those altitudes, . . . and the result of variation when applied as correction to those observed trigonometrical altitudes may be considerable." To show what he judges to be considerable may be added his further remark, "Mount Everest will probably prove to be some hundred feet or so higher than we at present reckon it."

Observe that Sir Thomas considers one hundred feet in 29,002 the present height assigned to Mount Everest, a considerable change in the altitude of that peak, which is the most extreme case of all on account of its great altitude, its distance from the measuring stations, and the large amount of moisture in the air above the hot, steamy plain of Bengal. He does not for a moment entertain the figure of 4,000 feet said to be suggested by the friend of the British Royal Engineer. If Sir Thomas's estimate be a probable one in this case, in the more favorable ones of lower summits measured from near stations the amount of correction would shade down nearly or quite to zero.

Now Miss Peck supposes an allowance similar to the friend of the Royal Engineer's 4,000 feet made to the ascertained height of Huascaran and asserts, "It might easily happen that the mountain is one or two thousand feet higher than it has been figured," which would bring it up well toward the altitude she has estimated it at. Such a supposition is not tenable. Even if the 4,000-foot statement regarding K 2 were true, the conditions in this case are entirely different. Her plan is ingenious but not creditable to her knowledge of the principles of altitude-measurement. Suppositions have no place in this field. Observed facts are what count.

M. de Larminat and his assistants, who are expert engineers and know what they are about, triangulated the two summits of Huascaran from four accurately measured stations at an altitude of 12,500 feet, in the immediate neighborhood of that mountain, in perfectly clear weather. Here was no immense distance, no haze in the air, no great height of the summits above his stations, as in the case of the great Himalayan peaks mentioned, to cause any appreciable chance of error due to refraction. Refraction in this case, if not allowed for at all, would be practically a negligible quantity. His results determined from four stations, three being usually considered sufficient to insure accuracy, must be exact to within a very small figure. Prof. Fr. Schrader and M. Henri Vallot of Paris, after a careful personal examination and checking of all M. de Larminat's observations and calculations, have indorsed them as correct. The indorsement of engineers of such worldwide reputation as they have is a sufficient guarantee of the accuracy of the work. Miss Peck may therefore rest assured that this triangulation will be accepted by engineers and experts as accurate and definitely settling the question of the altitude of the two summits of Huascaran.

Miss Peck makes two other statements, the relation of which to the altitude of Huascaran is not apparent: (1) That I "improperly claimed" a world record with 23,394 feet, and (2) that Mr. Graham's ascent of "Mount Kabru, about 24,000 feet, twenty years earlier, is now quite generally acknowledged." Mr. Graham on his return from the Eastern Himalaya claimed to have nearly ascended Mount Kabru as well as to have made a number of other high ascents. He gave an account of his experiences in London. His claims were very generally disbelieved at the time and afterward by mountaineers and engineers, and were especially disputed by the Indian Survey, the members of which were in a particularly advantageous position to judge of their truth. The grounds for discrediting his ascent of Kabru were several, but the strongest of all, well known to the Survey officials, has never, I think, been published, as the Survey did not enter the lists in print against Mr. Graham. Within two years I have had the opportunity of discussing the question with a retired surveyor general of the Indian Survey, who was in Calcutta when Mr. Graham returned from his attempt on Kabru, and he expressed his disbelief in the strongest terms.

Some time after the event Mr. Douglass Freshfield advocated Mr. Graham's claim, bringing forward no new evidence beyond Mr. Graham's original account, but basing his opinion on certain considerations of probability, which, though specious, were not conclusive and did not convince the public. He stood nearly alone for years. Recently a few of his friends have expressed their concurrence in his opinion, and in the United States Mr. E. S. Balch and Miss Peck have echoed the cry, though neither of them can have any knowledge of the question that can make their opinion regarding it of any value. The world at large has remained either neutral or disbelieving.

It is noteworthy that Mr. Graham had no instruments, not even an aneroid, with him by which to determine the altitudes he claimed to have reached, so that, as in Miss Peck's case, his ideas as to his altitudes were based wholly on guesswork. It is also significant, as an English journal recently stated, that after his account given in London, he never joined in the discussion that followed nor attempted by any further statement to defend his claim. Not long afterward he disappeared, and, so far as I have been able to learn, his whereabouts have since remained unknown.

Mr. Graham's account constitutes the only evidence available in the question. If anyone after reading this chooses to believe that his claim to have ascended Kabru is valid, he has a perfect right to do so, but such belief does not afford any proof of validity, nor does it warrant the person holding it in asserting that Mr. Graham's ascent "is now quite generally acknowledged." The only verdict that can be reached, as the matter stands, is that of unproven.

In stating the above facts I wish it distinctly understood that I am not expressing my own opinion as to Mr. Graham's claim. This I have nowhere done either in lectures or in writing, although such expression has been ascribed to me by others.

With regard to Miss Peck's repeated assertion that I "improperly claimed" a world record with 23,394 feet, my position may be stated as follows: Although, as a matter of fact, this altitude attained by me in 1903, was and remained for several years the highest measured altitude reached on an ascent, and although I had every right to publish it to the world as a record, with two exceptions I have never mentioned it as such either in public or in print, not even in the volume "Ice Bound Heights of the Mustagh," by Mrs. Bullock Workman and myself, in which I have described my ascent to that altitude. One exception was a mention of it in one of the issues of "Who's Who." The other was in connection with a paper on that ascent read before the Alpine Club in London in May, 1905, when I said:

"The word 'record' in the title of this paper is used as referring to the highest substantiated ascent yet made in mountaineering. The contention that Mr. Graham reached an altitude of 24,000 feet has on various grounds, whether rightly or wrongly, been so strongly disputed that it must be regarded as far from proved, and therefore the altitude mentioned cannot properly claim a place among those acknowledged to have been made."

In this year 1910, so far as Mr. Graham's claim is concerned, I see no reason to alter a word of that statement.

In view of the above I do not think it would be courteous in me to deprive Miss Peck of the distinction of "improperly claiming" a world record to which she herself has enjoyed a monopoly for the last two years. During that time her chief appeal to the interest of the public has been not by scientific observations on natural phenomena at high altitudes, but by constant reiteration in the press, without the authority of any measurement proof, of claims to the attainment of an altitude variously stated at from 25,000 to 23,000 feet, which finally crystallized into "It may be regarded as certain that Huascaran is above 23,000 feet. . . . If, as seems probable, the height is 24,000 feet, I have the honor of breaking the world's record for men as well as women."

Mrs. Bullock Workman's engineers have now stripped her claim of all ifs and probabilities and brought it definitely down to 21,812 feet, the altitude of the lower summit of Huascaran she claims to have ascended.

WILLIAM HUNTER WORKMAN.

### Effect of Rainfall on the Cotton Industry.

The amount of rainfall and the development of the cotton industry in any region are intimately connected. The first proof of this rather surprising assertion is found in the continual endeavor of inventors to devise means of giving to the air of cotton spinning rooms a proper and sufficient degree of humidity. But a deficiency of natural humidity cannot be perfectly remedied by artificial means, and it is a fact well known to all cotton spinners that the product of the spindles is considerably increased by the constant presence of a large amount of moisture in the air. The moist climate of Normandy has made that province the chief seat of the cotton industry in France, and for a similar reason Manchester has become the center of the English cotton manufacture. In addition to a moist atmosphere the cotton industry requires abundance of water in its visible form. Cotton mills are always located on or near streams and are provided with capacious reservoirs.

Hence the great diminution in the rainfall of the Manchester district which has taken place within the last half century is a valid cause for alarm. Hesketh has collated the records of rainfall made between 1860 and 1908. He finds that the mean annual rainfall was 36 inches between 1860 and 1886 but only 27 1-3 inches between 1886 and 1908. The observed shifting of one of the branches of the Gulf Stream is suggested as a possible cause of this great decrease in rainfall which threatens the industrial prosperity of Manchester and the surrounding district.—Cosmos.

## THE DISINFECTION OF RAILWAY CARS.

The running of a railroad in Germany is evidently accompanied with unpleasantness, if one may judge from the accompanying photographs The Potsdam shops, which are responsible for the proper maintenance of rolling stock, have been confronted with the difficult task of disinfecting the cars It seems that the coaches which return from Russia are literally a-swarm with vermin Even after the cars had been cleaned with true Teutonic thoroughness, there was still the possibility that living disease germs might lurk in the walls and hangings It was therefore the practice for some years to take down all the upholstery curtains etc and to clean everything thoroughly Naturally, the expense involved was heavy and the cars were withheld from service for a considerable time Moreover, there was also the danger of infesting the shops and other cars

The problem seems to have been successfully solved by Julius Pintsch who applied to the railway car a principle of disinfection which has been successfully employed on vessels His disinfecting apparatus consists of an iron cylinder built up of cast iron annular sections of 16 feet internal diameter The inside length is about 72 feet The cylinder is so stoutly constructed that it can easily support without deformation a 30-ton car

During disinfection the air within the cylinder is considerably rarefied by a pump, and as a result, the outer air exercises a pressure of about 1,900 tons on the disinfecting cylinder Since the apparatus is heated during disinfection allowance has to be made for expansion Hence the cylinder is mounted upon rollers, so that the apparatus can yield to an extent of about three-quarters of an inch in length, which is the amount of expansion

Before it is run into the cylinder, all the windows and transoms of the car are opened By means of a crane a two-ton closure is brought against the open end of the cylinder A rubber gasket is employed to make the closure hermetic Huge bolts hold the closure, gasket, and cylinder together Steam is blown into the interior of the cylinder Two hundred and fifty steam pipes line the interior of the cylinder, all receiving their supply from the main pipe The total length of all these pipes is about 1¾ miles In order to heat the air within the cylinder quickly and uniformly, two blowers are set in motion, so that all the air is brought in contact with the heating tubes Even during the coldest weather the temperature within the cylinder can be raised to 140 deg F in from one to two hours In order to heat an entire coach to this temperature, about five hours is required After the car has reached the proper temperature, the air is pumped out of the cylinder until a vacuum of 70 to 74 centimeters of mercury under the normal pressure is obtained At this atmospheric pressure water will boil at 104 deg F Hence all moisture is evaporated from the car without injuring the parts by the excessive heat In no other way is it possible to kill vermin effectually The upholstery curtains, hangings etc., are not in the least injured

For very special purposes the cars may be disinfected with formaldehyde gas At the very first attempt a car was thoroughly purged of vermin To make assurance doubly sure, and to test the efficacy of this formaldehyde disinfecting method a glass vessel full of the living insects had been purchased from a professional vermin-exterminator in Berlin This vessel was placed in the car and covered with cotton and linen The insects were all killed

The apparatus has also been employed to dry out wet cars as well as cars pervaded with the unpleasant odor of cooking After twenty-four hours they were quite ready for service again. In this case no formalin was used

The huge cylinder in which German railway cars are disinfected by steam and formaldehyde at Potsdam after their return from a trip to Russia.

Sealing the cylinder with a two-ton gasketed closure before exhausting the air and turning on the steam.

Liniment for Burns.—40 parts sugar lime, 10 parts glycerine, 50 parts carbolic acid oil, 3 parts salol.

## GOVERNMENT IRRIGATION IN THE YAKIMA WATERSHED.—THE TIETON CANYON CANAL.

BY DAY ALLEN WILLEY.

The region adjacent to the Yakima River in southern Washington is the location of a group of irrigation projects which are notable for the engineering features The topography of the country reveals a number of areas of arid land, separated by hill ranges which prevent water being distributed from a single source of supply The engineers of the Reclamation Service have made an investigation which extended from the lower portion of the Yakima River to its head waters in the foot hills of the Cascades, and have planned five reservoirs and distributing systems, which will have a capacity to irrigate no less than 350,000 acres, making this group of projects one of the most important in the West. The various works are the Tieton, Sunnyside, Wapato, Kettitas, and Benton They have a water supply through the rivers from four lakes and a submerged "meadow" having a total area of 574 square miles.

While the lower section of the Yakima River is used in part for what is known as the Sunnyside project, most of the service is performed by the Tieton, the Naches, and the Cowiche streams—small rivers which are feeders of the Yakima.

Of the projects, the Tieton is most interesting from a scientific standpoint, owing to the difficulties along the route, the various applications of power, and the fact that without the use of concrete the project would have been impossible This stream flows through a deep canyon with very steep sides, the height of the bluff ranging in places as high as 400 feet from the bed of the river to the level of the canal The water of the Tieton is diverted by means of a concrete dam thrown across the stream Although but three feet high and 200 feet long, the reservoir thus made is sufficient to fill a main canal 12 miles long and lateral canals having a total of 51 miles. In conveying the water from the dam to the point of distribution, the only practical route which could be located was largely along the side of the canyon near the top, the rim being of such formation that it would be impossible to build a tunnel or open canal upon it. Consequently, several miles of the conduit were supported upon hinges or arms of reinforced concrete anchored into the rock and extending outward from the canyon side. The Tieton project contemplates the irrigation of from 24,000 to 30,000 acres of land in the vicinity of North Yakima, Wash.

As the water is conveyed along the precipitous side hill of the Tieton canyon, for 20 per cent of the distance the canal lies in tunnels. The open canal sections are of semicircular form, 8 feet 2⅝ inches in diameter, with concrete shell 4 inches thick, while the tunnel sections are of circular form, 6 feet 1¼ inches in diameter, with concrete shell 4 inches thick This canal and tunnel lining are made up in 2-foot lengths, manufactured on the flats along the river bank, where concrete ingredients are readily obtainable, and lifted to the canal line by cable hoists operated by electric power These hoists are used successively at points about two miles apart, and the concrete shapes are transported along the canal between hoists on railroad tracks laid in the bed of this excavated route

This plan was adopted for the reason that beds of sand suitable for concrete were found in the bottom of the river In fact, the Tieton valley was made the site of a novel concrete works. The question as to how to transport them to the work was answered by the use of electrical power A series of tramways were built at convenient points up the side of the canyon operated by cable hoists These hoists in turn were served by a series of electric motors securing current from a power station constructed for the purpose The concrete as fast as mixed was molded to the proper dimensions in portable molds mounted on wheels, so that they could be drawn from place to place After hardening had taken place, the forms were set upon trucks having sides of steel framework These trucks were mounted on the tramway, and the material hauled to the top ready to be set in place.

On the Tieton project 10,000 feet of tunnel were necessary, divided into two sections of 3,000 feet each and one of 4,000 feet In excavating these much of the formation was found to be of black basalt rock requiring special machinery to remove it In making the tunnel excavation a circular bore 7¼ feet in diameter was driven by machine drills. Tieton River has a fall of from 50 to 60 feet per mile, and advantage was taken of this to develop the power required for operating drills and other machinery and for lighting purposes A power canal 3,500 feet long, of 180 second feet maximum capacity and 34 feet effective head, has been completed, which supplies water for operating a Franklin air compressor capable of compressing 1,250 cubic feet of free air per minute to a pressure of 105 pounds per inch, a Westinghouse generator of 120 kilowatts capacity, and one set of 26-inch twin turbines.

About 500 horse-power is developed, ample to operate the six electric drills, six air drills, shop machinery, pumps, hoists, etc., and to light all the camp buildings. The turbine is regulated by a governor, and the power canal is provided with an ample automatic overflow, just below the power house. An electric transmission line, carrying 2,300 volts, has been constructed to the upper portal of Trail Creek tunnel, a distance of seven miles. Electric drills are being operated at the two portals of Trail Creek tunnel, and at the upper portal of Tieton tunnel. At the lower portal of Tieton tunnel, and at both portals of North Fork tunnel, air drills have been installed.

Another difficulty in the way of building the Tieton project was the crossing of a number of ravines carrying small streams. A part of these were diverted into concrete flumes, while other conduits for them were made from rubble masonry These culverts are of the arched type and vary in width from two feet to eight inches, the size of the larger ones being necessary in order to allow for the flood currents through the ravines. The total expense of completing the

Tieton project is very small considering the work which had to be performed and the acreage which will be served by the water, a tract which will aggregate about 30,000 acres in all. In the construction work it was necessary to have a telephone line 33 miles in length, wagon roads along the route of the canal, and tunnels as well as temporary settlements for the workmen in the valley and on the rim of the canyon. The land, however, is especially suited to the raising of forage, fruit, and hops and is located on three important railroad lines having connections with the principal cities of Washington.

**Increased Cost of Army Rations.**

The numerous published accounts of high prices of food and the hardships which have been inflicted upon the workingman, and also the fact that hog meat has become so high in price that its use has been almost prohibitive, has resulted in a complaint from our Uncle Sam, to the effect that his army would have to substitute corned beef or corned-beef hash for bacon.

To those of us who served in the Spanish war, and had the canned or corned beef served us as a part of the regular ration, the news will not come as a surprise, but the man who reads this will undoubtedly think of the good beef he gets at home and wonder why complaints should be made.

One particular reason why the army will now use corned beef is from the point of economy, for as mentioned before the price of bacon has so increased as to make the change desirable.

The garrison ration is steadily increasing in price because of the general rise in the cost of food products. When the estimates for army subsistence were made last May for the next fiscal year, it was assumed that a ration would cost 20.97 cents. By January of this year the cost had increased to 22 cents, making it necessary for the War Department to submit a deficiency estimate to Congress. If the present rate of increase keeps up, the cost will be nearly 23 cents by the end of the next fiscal year. When it is considered that the army annually consumes several millions of rations, it will be seen that an advance of even a fraction of a cent in a single ration means a big advance in the aggregate for a year.

The canal consists alternately of open semicircular concrete conduits and circular tunnel.

Building the open section of the Tieton conduit. Note the wooden forms for the concrete.

One of the portable molds used in forming the concrete facings of the conduit.

The molding yard, showing the concrete lining sections ready for delivery at the canal.

The 4-inch concrete lining was built in sections in the valley and lifted to place on the side of the canyon.

Ointment for Burns.—Iodoform, 80 parts; extract of conii, 40 parts; carbolic acid, 1 part; rose unguent, 800 parts.

## HOW GAMBLERS CHEAT

BY HEREWARD CARRINGTON

Games of chance have always had a fascination for all classes of individuals, at all ages, and the professional "sharp" has made this weakness (which in some persons is developed into a ruling passion) a means for earning an easy livelihood at the expense of the numerous "flats" who visit the race course or other places where gambling is looked upon as a more or less legitimate pastime. The ingenious mechanical devices which have been employed for this purpose are really astonishing. Such clumsy appliances as loaded dice are, of course, out of date though one ingenious sharp invented a table the top of which was sheet steel under a very thin cloth covering. By means of an electro-magnet concealed within the table, its top could be converted into a powerful magnet, and the dice (which were prepared by having one side of metal while the rest were ivory) could be attracted to the table when the current was on or would fall in any haphazard position when the current was shut off. Dice, however, are generally suspected and hardly anyone would venture to stake money upon the fall of the dice any more than he would upon three card monte.

Cards are the most fertile field for the gambler's revenue. Winning at cards depends largely upon the possession of certain high cards or the aces which win the tricks and to gain possession of these cards is the gambler's object. For assuring this various devices have been employed called "holdouts," mechanical contrivances concealed in the sleeve which by a very slight pressure or movement in one direction, will instantly shoot out the required card into the gambler's hand and recede again into the sleeve. One of the most ingenious and perfect of these was invented by a gambler named Keplinger and the device has ever since been known as the "Keplinger holdout." The apparatus was worked by the knees, so that no motion of the arms or body was necessary. A slight separation of the knees was all that was required to shoot the card into the gambler's hand. The knees were thereupon relaxed and the "holdout" receded like a flash into the gambler's sleeve.

Another variety of "holdout" is that concealed in the waistcoat, and here the hand is held close to the body with the cards outspread while the thread is pulled, and in that manner a card shot into the hand under cover of the remaining cards. This however, is a dangerous procedure which is rarely employed. A small but ingenious species of "holdout" is that known as "the bag." The small sharp point seen in the illustration is stuck into the wood of the under side of the table in such a manner that the flat bar runs along parallel to and just touching the wood of the table beneath. One or more cards are now inserted into the clip thus formed, and may be withdrawn by the fingers in the act of drawing cards on the table toward the body.

A daring yet simple variety of "holdout" is attached to the sleeve. It is buckled around the shirt sleeve under the coat and two small pointed hooks facing outward press against the coat sleeve. These hooks may be separated or brought nearer together by pressing upon a small rubber tube. If now a card be placed against the coat sleeve, on the outside, and the clips separated and then released, they will clasp the edges of the card through the cloth of the coat, and it will be retained there by the pressure of the spring in the "holdout." So long as the arm be held *downward*, the card is invisible, but the card may be obtained possession of by the fingers of the other hand when resting against the sleeve of the arm to which the "holdout" is attached.

A still simpler device is to have a small pocket cut in the coat sleeve at the seam. The "pocket" is merely a slit about three inches long, into which the required card is inserted. The fingers grasp the card and withdraw it with the others at the required moment. Another variety of "holdout" is known as the "ring holdout." A ring is worn on one of the fingers, to the inside of which is attached, as part of the ring, a small wire clip or spring, flesh colored. The card is inserted under this spring, and in that manner is retained within the palm of the hand by the pressure. Experts in sleight-of-hand would not require a clip of this character, being enabled to palm the card without any mechanical aid.

Besides such devices as those just mentioned, the

THE ELABORATE OUTFIT OF THE GAMBLER.

gambler depends for his success partly upon his dexterity in handling the cards during the actual progress of the game. Of course marked cards are frequently employed for this purpose but the expert gambler will succeed in marking the cards with his thumb nail during the course of the play, so that, at the end of a few hands he knows practically every card in the pack from the slight indications upon its back. Sometimes, also cards are bent more or less slightly to insure their recognition—either individual cards or a number of cards together. If half a pack is bent in this manner this is called "the bridge." Each card in this section then has a slight curve, as shown in the illustration.

SOME GAMBLERS' TRICKS WITH CARDS.

A gambler may even deal to himself or to any person forming the circle a particular card which is known to him. This card is at the bottom of the pack, and the "sharp" deals off the cards from the top of the pack continuously until he reaches the person into whose hand he desires to place the card next to him, when, by a rapid movement, he withdraws, not the top but the bottom card with his fingers instead of his thumb. This trick, when rapidly and well executed, is practically undetectable.

Card "sharps" also employ other devices for gaining knowledge of the cards dealt to every member in the circle. In order to gain this knowledge, a small mirror is employed. Sometimes this mirror is attached to a needle point, and fixed to the under side of the table nearest the dealer. If, now, in dealing, each card be passed over the mirror in turn, the gambler will be enabled to tell the position of each card dealt, and to follow the cards before a single play can be made. A mirror of this character is a dangerous device, and it is easily detected. For this reason, very ingenious schemes have been employed. A small mirror is inserted into the bowl of a pipe, laid carelessly on the table, the bowl being turned slightly upward and toward the dealer. Now, in dealing the cards, they are passed each in turn over the bowl of the pipe, and in this manner the magnifying glass it contains conveys to the "sharp" all the required knowledge as to the cards contained in each sitter's hand. Occasionally "sharps" employ a mirror ring for this purpose, a large signet ring being used which during the course of play, is swung around so that the signet faces the palm instead of the back of the hand. The signet then swings open on a pivot hinge and discloses a tiny magnifying mirror beneath. By the aid of this mirror, the majority of cards can be detected as dealt. At least aces and court cards can be distinguished from cards of lower values, which is the chief thing to be discovered.

There are a number of other ingenious devices employed by professional sharps, but the above will at least give the reader an idea of the extent to which this practice has been carried, of the remarkable ingenuity displayed by manufacturers of such devices, and of the dexterity and daring of the gamblers themselves in employing them.

**Macrographic Examination of Metals.**—The macrographic examination of metals consists in examining with the naked eye the surface of the metal, which has been polished and chemically treated in such a manner as to bring out its constitution and its impurities. In micrographic or microscopic examination the particular objects of study are the character and chemical properties of the alloy, while macrography concerns itself with the physical properties. The principle of the methods used is as old as the first methods of damascening, in which an acid mixture was employed which blackened in different degrees the strips of iron and steel which had been welded together in the formation of sword blades.

The operations of macrography are essentially two: first, the preparation of the polished surface, which must be absolutely free from grease, secondly, the chemical treatment, which is preferably effected with dilute sulphuric acid, in which the entire piece of metal is immersed for several hours, or with an aqueous solution of iodine and potassium iodide. The indications furnished by the examination of the surfaces thus treated are useful in determining the quality of steel and detecting the presence of slag and of blowholes. When a bar of metal is cast there is frequently produced near the surface a blowhole which is filled with the more fusible impurities. Usually this pocket extends through one-third of the thickness of the bar. Macrographic methods show whether the blowholes have been obliterated either by pressure or by removal of the upper part of the bar, and they are also capable of detecting in forged pieces traces of these blemishes which have been left after the tooling.

The statistics of the American Railway Association show that the net surplus of freight cars on the railways of the country on February 16th was 14,809, as against 24,975 on February 2nd; 26,844 on January 19th; and 28,416 on January 5th. The increased demand for box cars and coal cars has [illegible] to call into service all [illegible]

### BIG FIR TREES OF THE NORTHWEST

The fir trees of the Pacific Northwest occasionally attain such proportions, especially in the territory near Puget Sound, that the stumps after the trees have been cut down are employed for novel purposes. In some portions of Washington one can see these huge stumps, which have been hollowed out and actually made into temporary homes for settlers. To make a stump house, it is only necessary to remove the material from the interior, leaving enough to form walls of suitable thickness Then a roof of boards or shingles is put over the top of the stump, holes are cut for windows and doors, and the dwelling is practically ready for occupation. A number of these stumps have been used by settlers on what are called logged-off lands, until they have been enabled to construct larger and more convenient dwellings. After the stump home has been vacated, it is turned into a stable for the horses, or sometimes into an inclosure for chickens or hogs.

Next to the big tree of California, or sequoia as it is termed by the scientists, the fir as found in Washington and Oregon has the largest diameter of any tree in America, and probably in the world Some have been cut down which actually measured 15 feet in diameter at the point where the incision was made As they decay very rapidly after the timber has been removed, usually the interior can be hollowed out with little difficulty Sometimes they are used for dancing platforms, as is shown in the accompanying illustration, some being large enough to accommodate four couples An other custom is to turn the big stumps into playgrounds for the children, who reach the top by pieces of wood nailed against the sides or by ladders, and a pretty sight which a traveler often sees in the northwest is one of the big stumps turned into a flower bed and covered with the trailing vines.

### How to Repair and Clean Typewriters.

BY LOUIS A. FLEMMING

As every user of a typewriter knows, the platen or roll is the part of the machine that wears out first The constant hammering of the type against the surface of the platen soon makes indentations in it, which in a short time amount to such a degree of roughness that it is impossible to produce good, clean work

A compound has recently been discovered that will restore the platen to its original smooth condition no matter how badly it is worn or how long it has been in use

The formula and method of using the compound are as follows The ideal material for use in repairing platens would be hard rubber, but in the process of vulcanizing, the rubber becomes insoluble to a great degree in the solvents generally used for making rubber solutions. As a substitute for hard rubber celluloid is recommended The hard variety should be used, which is sold under the name of imitation ivory This is soluble in acetone, amyl acetate, and various other solvents One of the best solvents is a mixture of eight ounces of acetone and one ounce of amyl acetate.

In the absence of anything else in the way of celluloid, any ordinary article made of this substance, as a comb, may be used There is a variety of celluloid used in the manufacture of combs which is quite satisfactory for this purpose The color also is good where this variety can be obtained.

In using celluloid on platens it is advisable to use something with it that will give it hardness, such as finely powdered silica, infusorial earth, emery, or other similar substances About one ounce of powdered emery to each eight ounces of compound is a fair proportion. Powdered soapstone also works well for the purpose.

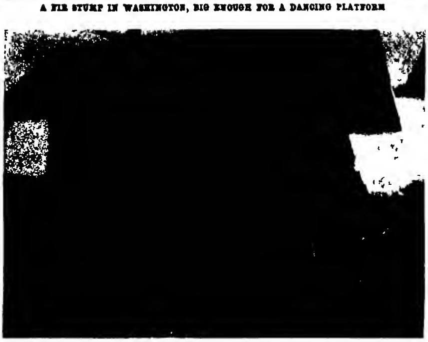
The celluloid solution should be made as thick as a very heavy syrup or molasses. In fact, as thick as may be spread with a brush The heavier it is when used, the sooner it will dry If a light colored celluloid is used, it is advisable to add some coloring matter, which may be lampblack or preferably gas or carbon black. Just enough should be used to give the desired grayish color Remove the platen from the machine The work may be done with the platen in the machine, but great care must be taken to protect the working parts from the dust formed when smoothing up It also takes less time to do the work when the platen is removed

Wash the platen with gasoline to remove all grease and dirt, and rub it with a piece of fine emery paper, to give it a new, clean surface With a brush, paint the mixture carefully over the platen, giving it a good thick coat.

Lay the platen aside for six hours or longer for the composition to harden Then with a piece of fine emery cloth smooth it down, taking care not to cut quite to the original surface of the platen This is the delicate part of the work, and upon the care used in doing it depends the quality of the job

Acetone and amyl acetate can be obtained at any drug store It usually requires from two to five hours for the celluloid to dissolve Breaking it up into small pieces hastens solution The solution should be prepared in a wide-mouthed bottle that can be securely corked It should be shaken often during the process as this will prevent the celluloid from forming in lumps The bottle should be kept tightly corked and away from fire, for it is highly inflammable Should the mixture become too thick, thin it with a little more of the solvent, if it is not thick enough, add more celluloid

A FIR STUMP IN WASHINGTON, BIG ENOUGH FOR A DANCING PLATFORM



STUMP OF A FIR TREE IN WASHINGTON WHICH SHELTERS A FAMILY OF FIVE

A cheap and simple cleaning compound for typewriters is composed of the following ingredients

| | |
|---|---|
| Paraffin oil | 1 pint |
| Benzol | 5 ounces |
| Cresol | 1 drachm |
| Kerosene | 4 ounces |

Mix thoroughly

This compound was for years a secret confined to one or two of the large companies that rebuild typewriters. The machine is immersed in the compound which quickly and thoroughly dissolves and removes all dirt, gum, grease etc It does not injure the enamel, but on the contrary improves its appearance making it as bright as when new In making up any desired quantity of this compound retain the proportions given in the formula, except that should a quicker drying mixture be desired the quantity of paraffin oil may be reduced and the kerosene increased In all cases the lightest grade of paraffin oil should be used and not the heavier lubricating oils If white paraffin oil is used a water white fluid is produced, if dark paraffin oil is employed the liquid has a light amber color Oil of citronelli or oil of sassafras may be substituted for the cresol which has no action whatever and is used simply to disguise the composition of the compound To use the compound fill a tub of sufficient size with it Place the machine in it and allow it to remain in the fluid for half an hour By lifting it up and down gum and grease will be washed off Then remove it and dry it with a soft cloth brushing the parts not accessible with the cloth About two gallons of the mixture are required in the average case. The compound may be used as long as any of it is left, as the dirt settles to the bottom of the tub and the clean portion may be drawn off It is necessary to keep it covered tightly when it is not in use to prevent evaporation of the benzol A fair preparation may be made by using one-third the quantity of paraffin oil mentioned in the formula an equal quantity of kerosene and from one and one-half to two times as much gasoline

### The Transformation of Sea Water Into Fresh Water

The belief was prevalent among the savants of the 17th and 18th centuries that a hermetically sealed earthen vessel dipped into the sea would fill itself with fresh water At the present day it is difficult to say on what this belief was grounded It surely could not have been evoked by experiment In a similar sense Marsigli, the founder of oceanology made in the year 1725 an experiment which effected the filtration of sea water through a system of fifteen pots filled with washed garden-earth or sand and so placed as to let the water fall as if in a cascade It is stated that the palate disclosed a definite diminution of the presence of salt Similar assertions are everywhere current among seamen

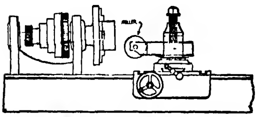
A scientific test of the endeavor to free salt from water was recently made by the French investigator Thoulet His report which appears in the minutes of the Académie des Sciences of Paris states that the presence of salt can be reduced by filtration Forty centimeters of the length of a glass tube which was one meter long and was placed in a perpendicular position was filled with sea sand and the rest of the tube was filled with sea water portions of the filtrate were examined at intervals of the experiment to ascertain its density and chemical composition The result was that in the initial stage of the experiment density as well as saline content were found to be moderately reduced very soon thereafter both recovered their original value The early decrease of value is explained by the mechanical attraction which every chemically neutral body exercises on the molecules of a substance in solution as soon as the body comes in contact with the solution In nature too sand fails to effect the separation of salt Through shipwrecked seamen it became known that relatively fresh water may be found on very low and barren coral reefs in the Pacific Ocean by digging to a trifling depth in the coral sand It is not however as was supposed sea water freed from salt through the layers of sand but is simply rain water that is retained by a sandy stratum and by it protected from admixture with the sea water Similar phenomena may be observed on the European coasts They may be considered the key to the popular belief now contradicted, that sea water can be sweetened by filtration through sand

According to the Electric Railway Journal, a novel type of electric locomotive has recently been built for canal haulage near Bremen The locomotive runs on a quay which has to be kept clear for the passage of drays and for other purposes To secure the necessary weight for adhesion it was decided to build the locomotive in the form of two U's with a connecting girder The current is taken from overhead wires.

### A TOOL FOR CENTERING WORK IN A LATHE

BY H D CHAPMAN

The accompanying drawing shows a handy tool for centering work in a lathe chuck When a job is to be faced off it requires a little time to get it to run

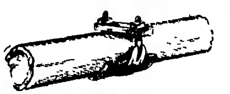


SIMPLE METHOD OF CENTERING WORK IN A LATHE.

true The drawing shows how the work can be expedited by the use of a simple tool The tool is made of tool steel, the roller is hardened When a job is placed in the chuck to be faced off and the face of the work does not run parallel with the face of chuck the roller tool is secured in the tool post, and the lathe carriage is then run up by hand until the roller strikes the face of the job As the work wobbles in the chuck the high position will be struck by the roller and forced true with the face of the lathe After the work has been trued it is then ready for machining

### REPAIRING A LEAK IN A STEAM OR WATER PIPE

A sandhole will occasionally cause a leak in a steam or water pipe, after the piping has been put up and perhaps been in use for a considerable time It can be repaired with an ordinary carriage clip and yoke



MENDING A STEAM OR WATER PIPE.

and bit of sheet rubber packing, although a piece of an old rubber shoe would last for years

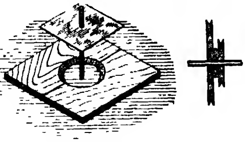
You can readily see the application by referring to the sketch The writer stopped two leaks in steam pipes fifteen years ago by this method The pipes have been in service ever since and have not leaked They were both in rather inaccessible places, where it would have been difficult to renew the pipe At the same time being in out-of-the-way places the appearance of the patch did not matter

### GROOVED PULLEYS FOR EXPERIMENTAL WORK

BY CHAUNCEY W NIKMAN

Small grooved pulleys or sheaves can of course be turned on the lathe but a substitute for the lathe which in some respects is quicker and cheaper, will be found very advantageous The description of such a method follows

In a piece of wood of the thickness desired for the pulley bore a hole of a diameter equal to that of the pulley at the bottom of the V-groove With a half round rasp or large drill countersink this hole on both sides Split—do not saw—the board in two down the



MOLD FOR CASTING PULLEYS.

middle of the hole, then nail or clamp it tightly to a smooth board the two halves being pressed firmly together Find the center of the hole with a compass and drive in a headless nail taking care to get it vertical, to serve as a "core" for the bearing Have handy a piece of cardboard considerably larger than the pulley, with a hole in its center the size of the nail Pour melted solder into the mold, and quickly slip the cardboard over the nail and down upon the mold This will force out superfluous metal and make the upper side of the pulley smooth When cool, unclamp the mold and pull apart where split. A knife or rasp will then do all the finishing necessary Two or more pulleys can be cast together by placing the molds one upon the other, with their centers common. The figure shows such a combination. A hub may be made in a similar way If a stronger bearing is wanted, as for an idler, wrap a strip of brass around the nail and let it become soldered to the metal

Along similar lines a cogwheel may be cast, but great care is necessary in cutting the teeth in the wooden mold A large number of pulleys can be cast from one mold, and for duplication work this method will be found quicker than the lathe.

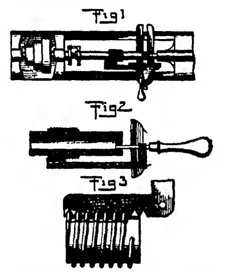
### HOW TO CUT THREADS WITHOUT A SCREW-CUTTING LATHE OR THREAD-CHASING TOOL

BY JOHN BERGSTROM

The ordinary way to cut a thread by hand is to use a thread-chasing tool with the number of teeth per inch wanted The difficulty in chasing a thread is in the starting It takes a great deal of practice, and even then a "drunken" thread may be the result

The accompanying illustrations show how this can be done in a very simple way and yet give an absolutely true thread

If a number of screws are to be cut the best way to proceed is as follows Take a thin piece of tubing that will just fit over the bar or bolt to be threaded In one end drill a small hole, into which fasten the end of a spring brass wire, preferably by soldering Then wind the wire around the tube half a dozen or more turns Now take a thread gage Select the number of threads per inch wanted and place it lengthwise of the tube, bringing one turn of wire in each



SCREW-CUTTING ATTACHMENT FOR LATHES.

notch, after which pull the free end of the wire and keep it tight Solder the coils to the tube, using only the corner of the soldering iron then move the gage one-third of a turn around the tube and repeat the soldering and finally move the gage again an equal distance and solder

It will now be seen that there is a perfect thread or spiral around the tube, which we will call the master thread This master thread must be slipped on the bar or bolt to be threaded so that it will not turn, allowing enough room at the end for the threads to be cut. The cutting tool consists of an ordinary hand tool, with only one point. Procure a small piece of wood, long enough to reach over the master thread and to the end of the bolt. Into this piece of wood drill a hole just large enough for the cutting tool to slip through and fit snugly

In operation the cutting tool is held in the right hand, in the usual way Then with the left thumb press the piece of wood against the master screw and start up the lathe The master screw will feed the cutting tool the right pitch As soon as a good start is obtained the tool will feed itself without the aid of the master screw

When the thread is finished the master screw may be removed and slipped over another bolt to be threaded The spiral may be wound right or left, according to the direction wanted Any number of threads may thus be formed That is to say if a triple or quadruple thread is wanted, it is only necessary to wind three or four wires around the master thread and proceed as before described This arrangement is also very handy in starting a thread when the ordinary chaser is used, as it will always insure a straight thread It is not necessary to nick or mark the wooden block, as it readily takes the impression of the thread from the master screw

Fig 1 illustrates a plan view of an ordinary lathe, ready to cut a thread Fig. 2 shows how internal threads may be cut and Fig. 3 shows the master thread.

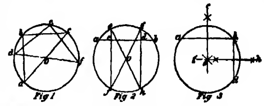
### SIMPLE METHODS OF FINDING THE CENTER OF A CIRCLE.

BY AUGUST MENCKEN

Very often it is necessary in the drawing room or shop to find the center of a circle, a disk or a piece of shafting, etc., when the diameter is not given Below are three ways in which this can be done

The first, Fig 1, is the method usually used It consists of two right triangles drawn so that their angles are in the circumference of the circle as *a b c* and *d e f* The point where their hypotenuses intersect is the center of the circle

The second method is shown in Fig 2 Draw any chord as *a b* and take two points on it as *c d* equidistant from its ends. At these two points erect perpendiculars to *a b* cutting the circle at *e f g* and *h* Then



THREE WAYS OF FINDING THE CENTER OF A CIRCLE

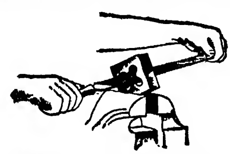
draw *e h* and *f g*, and the point where they intersect will be the center of the circle

Fig 3 is similar to Fig 2 Draw any two chords as *a b* and *c d* and at their centers erect perpendiculars to them The point where the perpendiculars meet will be the center of the circle

### HOW TO SHARPEN A PIPE DIE.

BY ALFRED F BISHOP

I discovered a short time ago that a mill-cut file would sharpen a solid pipe die quite easily and quickly without removing the temper in the die The first few rubs of the file will slide without cutting, this being due to the grease on the die Just as soon as the greasy surface is thoroughly worked off,



A PIPE DIE CAN BE SHARPENED WITH A FILE.

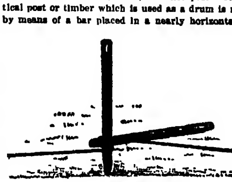
the file will commence to cut, and will cut very smoothly making a keen edge on the cutting thread Heretofore I have always worked on emery grinders to try to do this work without removing the temper of the die, but found they worked very slowly on account of the small diameter of the wheels, also that it was quite a nuisance to set the die for the cutting wheel Most mechanics would not try the file not having the least idea that it would do the work That was my case.

### A "SPANISH WINDLASS."

BY GEORGE H M'ENTIRE

Herewith is a sketch of what is known among cowboys as a "Spanish windlass "

One end of the rope is made fast to the load, the other to a "dead man," tree, or fence post The vertical post or timber which is used as a drum is rotated by means of a bar placed in a nearly horizontal posi-



A "SPANISH WINDLASS."

tion bearing against the vertical post but not fastened to it. The rope is passed around the end of this horizontal bar

One man holds the post against the ground and vertical, and a second man walks around with the bar passing it above the rope, and thus winding the rope on the vertical post.

The whole windlass moves toward the "dead man" as the rope is wound on, so no permanent hold can be

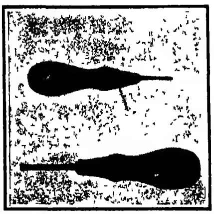
made in the ground for the vertical post to turn in.

This windlass is very useful for pulling wagons and autos out of the mud. All one needs is a rope and two posts or timbers.

### THE WEIGHTING OF TOOL HANDLES.

BY A. J. JARMAN

How often it occurs that when a tool such as a brad awl or particularly a keen-edged chisel is thrown down in a hurry it will roll off the bench and fall upon the floor, perhaps into a glue pot or upon the foot of the workman, or on a hard surface that will nick or dull the cutting edge. The following little scheme is employed with all the wood-working tools of the writer and found to answer admirably. Bore a hole in that part of the handle that rests upon the bench, with a five-eighths rather dull cutting twist bit. Bore the hole only as far as the center of the handle, but no farther, or the object desired will be defeated. A dull cutting bit makes a rough-sided hole. Into this pour some melted lead (of course the lead should not be too hot). When the lead becomes set, trim it off evenly with a fine rasp and finish off with coarse sand paper. Now when the tool is thrown down hurriedly upon the work bench it will not roll over more than once and will come to rest leaded side down. This little dodge is not only inexpensive, it is thoroughly effective, it will not only save annoyance, it will prevent many an accident, which no one can realize more than the man who is handy in the use of wood working tools.



BRAD AWLS WITH HANDLES WEIGHTED TO PREVENT ROLLING.

The illustration shows two brad awls, fitted as described, and used by the writer for several years.

### AN ILLUMINATED GAS HEATER.

BY F. G. WILLIAMS

The accompanying illustrations show how an illuminated gas heater can be made. The heater is mounted on a suitable pedestal, such as a wrought-iron stand or a base of some old discarded oil lamp. The heater proper consists of a burner *A*, a screen *B*, and an outside cover or shield *C*, which is removable. A suitable handle is provided at the top of the cover for this purpose.

Through the base passes an ordinary gas pipe, and at its lower end a stop-cock is fitted with a suitable attachment for a rubber hose so that it can be connected to the gas supply in the usual manner. At the upper end of the gas pipe is attached an adjustable sleeve for regulating the proper proportion of air to be mixed with the gas. The sleeve terminates in the burner proper, which is made with double walls. The lower part is made conical, so as to better distribute the mixture of gas and air. The burner proper is made from ordinary culinary utensils, the inside part from a small pan, and the outside part is made from a colander with very small holes, the smaller the better. These two parts are riveted together at the top, so as to make them tight. The lower or conical part may be made from ordinary black iron and may be fastened to the upper part as well as to the lower or gas pipe in any suitable manner, as by riveting or seaming.

The screen is made of wire netting fastened together, forming a cone with the same taper as the burner. The upper strands are bent inward so as to serve as a support for the cone. On this screen long asbestos fibers are attached. The raw Canadian rock asbestos is procured and the fibers pulled out in long threads, sometimes two or three inches long. These fibers are fastened and spread all over the surface on top of the perforations in the burner, and when the gas is lighted an incandescent mass will be formed which radiates heat but is not consumed. The outside cover is also made from some sort of pot or pan, provided at the top with a suitable handle, terminating with a downwardly extending rod, which passes through holes in the top of the burner proper and fits into a small socket at the lower or conical end. This is for the purpose of keeping it securely attached to the same. A number of holes at the top should be made for the circulation of the air and spent gases.

The cover may be cut out or perforated in such a way as to represent a landscape or any conventional design. The inside of the shield may be lined with mica so as to render the heater more safe. The mica may be tinted in almost any color desirable. Aniline colors are dissolved in amyl acetate, then mixed with amyl acetate collodion (commonly called banana oil). This mixture is applied with a soft brush and will dry very smooth. It will withstand a great deal of

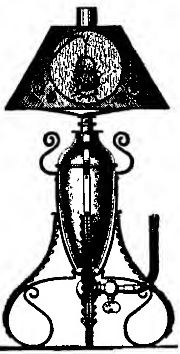


Fig 1

A GAS HEATER IN THE FORM OF A LAMP

heat. When the burner is lighted the gas will burn and form small blue beads on the outside of the perforated burner, and as the flame strikes the asbestos fibers it will make them glow very brilliantly and change colors as the fibers are moved to and fro by the currents of air passing between the cover and the burner.

If artistically made the heater may be used on the top of a table and will be a real ornament to the house but, of course, will show off to a better advantage in a dark room. The outside cover is not at all necessary, but is only used to get the desired effect.

SECTIONAL VIEWS SHOWING DETAIL OF CONSTRUCTION.

### FILES AND THEIR USES.

BY HOMER CLOUKEY

Nearly everyone who has had much filing to do, knows what a difficult thing it is to get hold of a reliable handle. Wood ones will split even if ferruled, or the brass ferrule will become battered and weakened. Steel ones are rarely satisfactory, and the set screws are always in the way. The following is a simple method of reinforcing the file handle: At the end of the file handle turn two ⅛-inch grooves, placing them ⅛ inch apart. Connect by two diagonal grooves of the same size, wrap with a piece of paper, and pour Babbitt metal or solder in the top. Trim up, and you have an everlasting file handle.

A simple and inexpensive file cleaner is made by hammering either end of a medium or large sized common wire nail until it is flat. This tapering flat piece is then trimmed off square, with a file, and filed to an even thin edge. This cleaner is self adjusting to all files and is far more effective than the expensive wire brushes usually used.

Files as nearly everyone knows are made from the best of tool steel to hold a sharp and strong edge under tremendous strain. This steel primarily has to be capable of being easily worked and, after it is worked, of holding the finest temper imaginable. It will be seen therefore that it must necessarily be the best of raw material for the articles enumerated below. It must be remembered that files have a very high temper, and therefore in all operations in which this degree of hardness is not essential, the temper should be drawn by heating and cooling down slowly in order to render the steel less brittle. In fact, the temper and quality of a good file are instanced by the fact that the writer has seen made and has tried satisfactorily a razor ground from a 10-inch flat mill file on a regular emery wheel and then honed and stropped into shape.

Perhaps the first use I ever saw old files put to was a full set of nail sets made from 6-inch triangular files by snapping them off to an even length at five inches and grinding the points down to various sizes required. The top ends were rounded off nicely, and the teeth were ground just enough to give a beautiful knurled effect to the set. I asked the mechanic who made these tools why he hadn't used rat-tail files and make them round, but he said he just wanted them different from the common run of tools. Some years later I did have the pleasure of seeing a beautiful set made from round files. Only with these there was left an unground strip between the two ends, to afford a good grip for the fingers.

Another splendid set which was evolved out of files

REINFORCED FILE HANDLE.

by a machinist who had occasion to do a little special pattern making from time to time, was a complete set of little V-shaped gouges and flat chisels and half rounds, all made with curved shanks to reach otherwise inaccessible places. These were made by forging small files of the requisite cross section into the curve required, and grinding the shank and edge to the tool desired. By requisite cross section I mean that he always took a flat file to make a flat chisel and a triangular one for a V-shaped one etc. When these were ground nearly to their finished sizes he hardened them by suddenly cooling in oil from a cherry red heat, and then tempered them to a medium straw and again cooled them, after which they were given their final grinding and sharpening. The tang on the file was just the thing to fasten the finished tool in a firmly ferruled handle, and his tool was complete.

If you want a good heavy center punch, snap off either a rat tail or triangular file of the right size to a convenient length, say five inches; grind a good long taper on it up to the last ¼ of an inch, and make the taper shorter to give more metal to the point, and there you are.

Sometimes a file will help out a serious difficulty if it is only used. An occasion arose in which it was absolutely necessary to shear off some large spikes in some built up timbers that had already been placed in a building. It looked well nigh impossible until I thought to sharpen a file to an edge on the blunt end similar to a cold chisel, and by driving this in between the piles it was a simple matter to cut the spikes, though to tell the truth it spoiled the edge of the file several times before they were all cut.

Perhaps the most common use to which they are put is to make them into burnishers for sharpening cabinet scrapers and kindred tools. For these they are simply mounted in a handle and ground until they are perfectly smooth. Triangular files are the ones commonly used for this purpose.

A round file makes an efficient awl for any purpose and with scarcely any trouble to transform it ready for its new duties as it needs only to be sharpened.

An amateur desiring to take up brass craft work, and not wanting to pay the exorbitant price generally exacted for an outfit, decided to make one from files. In less than two hours he had made every tool illustrated in a large assortment, and they were a creditable-looking outfit, comprehensive enough for any ordinary purpose, and included all the customary piercing, denting, tracing, and stippling tools.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

HAT PIN ATTACHMENT.—[illegible] LOCASCIO, Baltimore, Md. This improvement provides a guard to be fastened over the point of a hat pin for protecting the latter from injuring persons in the vicinity of the wearer. The device can be applied directly to the point of the ordinary hat pin or removed instantly without screwing the guard to the pin or fastening it in any other way than by a slight pressure.

### Electrical Devices.

COMBINED SPARK COIL AND INDICATOR.—T. A. THORNDIKE, Randolph, Neb. In this case the invention relates to electric spark devices, Mr. Thorndike's more particular purpose being to combine a spark coil with an appropriate indicator for disclosing the condition of the coil in order that the operator may readily ascertain if the spark is being made properly.

### Of Interest to Farmers.

FRUIT-GATHERING VESSEL.—J. H. O[illegible], [illegible], Wash. The device is for use in gathering fruit, vegetables, and the like. The inventor employs a body portion which is in the form of a metal or other pail which enlarges or tapers towards its lower discharge end so that the fruit may be freely discharged without bruising, binding, or choking in the discharge, and the pail is preferably made of an elongated oval form.

ELECTRIC VACUUM MILKING MACHINE.—H. H. [illegible], Duquesne, Pa. This device is to a certain extent automatic in its operation and does not therefore require so much the service of an attendant. The invention provides a special form of electro-magnetic automatic vacuum shut-off valve for stopping the action of the vacuum on the cessation of the flow of milk, thereby avoiding all danger of injury to the cow which may be sensitive to a continued operation.

### Of General Interest.

FUME ARRESTER.—[illegible] WHITMORE, Butte, Mont. More especially this invention is applicable to those furnaces in use in smelters in which certain ores are roasted which give off gases and fumes that are injurious to vegetation and which tend to render the atmosphere of the surrounding locality unfit to breathe. The device may be attached to the furnace of the ordinary smelter and by which the smoke and gases may be condensed and the injurious substances extracted.

COMPOSITE FABRIC.—[illegible] STRAUSS and W. H. [illegible], New York, N. Y. This invention pertains to a fabric of the elastic type. An object is to provide a fabric which is strong, durable, and inexpensive to manufacture, and a fabric of high elasticity which will stretch readily without tearing the non-elastic components thereof.

DOOR-STAY.—M. LOGAN, Plymouth, Ind. The invention relates more particularly to stays such as are adapted to be used on gates, screen doors, or the like whereby the doors are braced to insure their being evenly supported in normal condition. The aim is to provide a device which will prevent a door from sagging and which will always permit it to swing freely while being opened or closed.

SMOKING-PIPE.—[illegible] KEEN, Franklinville, Pa. The principal objects in view are to provide a pipe which may be readily cleaned, one in which the nicotine-bearing liquid of condensation is trapped in a member from which it is readily and quickly drawn, and to provide a construction whereby the ash and coked particles of the pipe structure may be readily removed.

COMPOSITION.—W. H. H[illegible], Springfield, Mo. The invention refers to waterproof polishing compounds, and it consists in ingredients which are compounded in specified proportions. An object is to provide a metal polish which has the form of a paste, and impervious to water. A further object is to provide a compound which cleanses as well as polishes.

COMB.—J. W. [illegible], Chattanooga, Tenn. This comb is fashioned preferably from metal and formed from teeth assembled upon a rod, the teeth being suitably spaced and forced to attach to the rod under pressure, thus obviating the manufacture of the comb from the single piece of material while resulting in the production of an article substantially equal to one formed from a single piece.

SPIROMETER.—J. D. CHILDS, Chester, S. C. This invention comprises a cylindrically formed apparatus and is intended for use in the exercise of increasing the lung capacity of the party using the spirometer. There is very little space left between the movable part and the fixed part of the device, and when the movable part is in a certain position but little air remains to become putrid. A suitable mouthpiece is connected with the free end of the hose.

DISTILLING DEVICE.—O. A. NENNINGER, El Paso, Texas. This apparatus comprises means for boiling water and adapted to connect either with a still or with the hot water boiler of a kitchen range when there is no fire in the range. A connecting system of valves and other appurtenances enable the desired connections to be readily made by throwing a handle member which controls the valves.

SHOW-CASE.—A. RAINES, Baltimore, Md. This invention is an improvement in show-cases such for instance as the ordinary inside show cases and cases in the form of show windows and the like. The inventor provides a channel strip which fits over the edge of one glass plate and is connected with the under surface of another. Cement is used within the strip and secures the latter in connection with the glass plate. In repairing or replacing glass a facing is used which can be severed by means which avoids cutting the cement, which is difficult when the compound has hardened.

RAISING DEVICE FOR MOLDS.—J. S. LISTON, Anderson, Ind. The aim in this invention is to provide a device for building a reinforced wall of concrete or the like, the mold thereof being adapted to be raised from and over the concrete wall after the same has sufficiently set and constituting the form for a second section of the same wall, and so on upwardly until the wall is completed.

NECK-YOKE.—J. [illegible], Silverton, Colo. The improvement is in neck yokes, and particularly in centers, and has for an object to provide a novel construction of neck-yoke center which will possess the maximum strength as well as be flexible in all directions. The neck yoke center is made of harness and sole leather.

WATCH PROTECTOR.—B. [illegible], Philadelphia, Pa. An object of this inventor is to provide a watch protector for convenient and secure attachment to the pocket of a vest or other garment, and arranged to permit the wearer of the garment to conveniently place the watch in position in the protector or remove it therefrom and to prevent abstraction of the watch by pickpockets or unauthorized persons.

FOLDING BOX.—F. G. FISCHER, New Haven, Conn. The improvement provides a box having an inner compartment extending [illegible] from the box; provides a box the outer wall of which is so constructed as to form no visible joint; provides a construction wherein both the inner and outer walls of the box are provided with openings which aline, and provides a construction having a hinged cover having the four structural sides firmly secured to form a rigid structure.

PIANO VIOLIN.—L. BARTENSCHLAG, Napoleonville, La. The invention is an improvement in violin pianos, and the purpose is the provision of an instrument consisting of strings arranged and tuned like the strings of a piano and vibrated by a rubber instead of a hammer, and when the resulting tone will approach that of a violin.

MOLD FOR CEMENT BLOCKS AND WALLS.—C. A. TORRANCE, Gibbon, Neb. Mr. Torrance's invention is an improved collapsible core for use in molding hollow cement blocks and building blocks. In building a hollow cement wall or in forming a hollow cement building block, the body of the mold employed being placed in position, the collapsible core is then adjusted in place in the center of the same, its sides opened or distended, and by the aid of other means provided a hollow wall may be built up to any required height.

### Hardware and Tools.

SAFETY RAZOR.—I. NARESMOW, New York, N. Y. By this invention the cutting edges of the blade are retained close to the guard plate at all times during the use of the razor, and each guard or guard plate is made as a separate section with means to spread the sections apart or move them together according to whether a close shave or otherwise is desired.

CLOSURE REMOVER.—F. MARTIN, Sherrill, N. Y. The invention has for its object to provide for a device for removing the covers of fruit jars and the like, without fear of damaging the jar or injuring the hands. It can be quickly affixed to a jar and by slightly pressing downwardly on the handle of the implement the cover is loosened and raised from the jar.

COMBINATION LOCK.—S. N. FRIEDMAN, New York, N. Y. This is a keyless lock having a simple combination which must be known before the lock can be opened. An object here is to provide a lock with a push button attachment by means of which an electric bell or annunciator may be rung, and to provide an arrangement whereby the electric bell may be rung if the knob of the box is tampered with.

BIT-BRACE.—C. R. COFRANO, Crescent City, Cal. The objects of the present invention are: To provide an implement which quickly and easily may be converted from a carpenter's brace for use with a bit to a gear-driven breast drill, and to simplify the construction so that the disadjustment of the parts is minimized.

MOUNTING FOR CASTER WHEELS.—J. SHARON, Canaseraga, N. Y. This inventor provides a mounting which may be placed in an operative and inoperative position successively and held in each position securely; provides a mounting which may be quickly and readily adjusted to form a solid bearing for the caster, and provides a mounting durable and of economical construction.

HORSE-COLLAR FASTENER.—A. J. DAINS, Pratts Fork, Ohio. The aim in this instance is to provide a fastener by means of which the collar can be expeditiously secured in position upon the animal and be easily released to permit the removal of the collar, without a loss of time, and labor, and in which the parts are securely held together when joined against accidental release.

HAND-TRUCK.—T. C. FASSBICKERS, Astoria, Ore. This invention provides a braking device for hand trucks which will automatically operate on downwardly inclined surfaces; automatic devices for hand trucks which are graduated in their operation in conformity with the position of the body of the truck relative to the ground, and to simplify and economize the construction of the truck.

### Heating and Lighting.

SUCTION-NOZZLE FOR DUST AND ASH REMOVING DEVICES.—E. PASSERNBOSS, Syracuse, N. Y. The purpose of this inventor is to provide a dust and ashes suction nozzle and its combination with air exhausting means, which enable the speedy and thorough removal of fine ashes from the ash pit of a furnace or the like, and the transfer of such material to a point of discharge.

MEANS FOR FACILITATING THE REMOVAL OF ACCUMULATIONS IN THE PIPES AND ELBOWS OF FURNACES.—F. PASSERNBOSS, Syracuse, N. Y. The intention in this case is to provide openings in the hot air conveying pipes and draft pipes of hot-air furnaces, and novel means for closing such openings so as to prevent leakage, and further to provide similar openings and closures for the elbows of the draft and hot-air pipes for air heating furnaces.

MINER'S CANDLESTICK.—A. R. SHARP, Boise, Idaho. The purpose here is to provide a candlestick which can be suspended from a suitable support which can be driven into a wall or the like to hold it rigidly in place which has means for securely holding the candle, and the parts which are removably held together to permit the candlestick to be taken apart.

CHIMNEY.—J. D. WARREN, New York, N. Y. The invention refers to chimneys adapted for use with liquid or gaseous fuel burners and more particularly to chimneys for gas burners with which incandescent mantles are employed. The object is to reinforce and strengthen the base portion of the chimney and provide means whereby air may gain access to the interior thereof to support combustion.

### Household Utilities.

HOOK RACK.—E. OLDENBURG, New York, N. Y. In its preferred form the improved rack has two separate end plates foldable into engagement with the base, and this base is formed of telescoping members relatively movable to vary the total length of the rack. The object is to render the rack simple and durable in form and approximately all of the parts of sheet metal.

MATTRESS.—A. T. QUICK, Lynchburg, Va. This ventilating device for use in mattresses comprises a tube provided near one end with a circumferential series of openings, a button having a channel receiving such end of the tube, and also provided with inner and outer spurs bent from the inner and outer sides of the tubes through the openings therein, and a gauze cover within the ring and held by the spurs thereof.

FASTENING DEVICE.—MARY O'DONOVAN, New York, N. Y. The device is more especially designed for use on ironing boards to permit the user to conveniently and quickly fasten the cloth cover in place on the ironing board or to remove the same from the board for cleaning, renewal or other purpose. The device permitting the user to properly stretch the cloth cover and to hold it in a stretched position.

BED-RAIL FASTENER.—F. W. MERRIWEATHER, Kansas City, Mo. Generally speaking this invention consists of a rail having a head secured thereon, a bolt secured in the head, said bolt being adapted to engage a slot or socket in the end of the bed, and a wedge adapted to cause the bolt to secure the rail and the end tightly together.

### Machines and Mechanical Devices.

ROLLER BEARING.—J. RAMSEIN, San Mateo, Cal. The invention relates more particularly to that type of bearing in which are provided two bearing members or racings separated by a plurality of rotatable load supporting members, and in which those members are spaced apart by intermediate rotatable spacing members. Means provide whereby the rotatable spacing members will have rolling rather than sliding engagement with every part with which they connect.

ROAD-GRADING MACHINE.—B. WHITTEMORE, Albert Lea, Minn. The object here is to produce an implement which is simple and can be readily operated so as to grade a road. The general structure is such that the material of the road bed is scraped from the sides and brought inwardly to the middle portion or crown of the road. Means provide particularly for adjusting the parts and controlling the distribution of the road material.

EXPOSURE ATTACHMENT FOR PHOTOGRAPHIC-PRINTING MACHINES.—E. N. KEAN, Rock Island, Ill. The machine enables the operator to adjust the time of exposure, incidental to the photographic printing with a high degree of accuracy. It automatically cuts off the light and thus ends the exposure of the paper or other article being printed.

PACKAGING-MACHINE.—R. HOEY, New York, N. Y. The invention refers to machines for packaging more or less finely divided materials, its principal object being to provide such an apparatus in which the operations of forming an envelop or wrapper, supplying the contents, and closing and delivering the package are continuously and automatically carried out.

GAGE FOR SEWING-MACHINES.—J. L. KLEINMAN, New York, N. Y. The object of this inventor is to provide a gage for use on the presser foot of a sewing-machine, and arranged to insure accurate guiding of the fabric material with a view to locate the row of stitches the desired distance from the edge of the fabric material or parallel to a previous row of stitches.

PUMP.—T. J. JOHNSON, Norman, Okla. In operation the straight arms move the pistons in the cylinders, and the weights on the respective sides of the frame are so proportioned, that when one side moves downward, its weight of water serves as power to lift the water on the other side.

WATER MOTOR.—C. A. WHELAN, Buena Vista, Colo. The casing of this device with the rotor in place, is arranged in the current, or the path of the movement of the waves, with the inlet end up stream. The water flowing strikes the blades, and since they are arranged at an angle to the lines of force exerted by the current, they are deflected to one side, thus imparting a rotation to the casing, which movement is transmitted by the shaft to the mechanism to be operated.

POCKET CASH-REGISTER.—K. SCHAUB, Kansas City, Mo. In carrying out this invention Mr. Schaub provides a number of wheels, upon the margin of which are certain figures representing monetary values. These wheels are operated by means of a series of rods or plungers and when so operated are turned to register the amounts expended, such registerings appearing in openings in the casing of the device.

SAWMILL SET WORKS.—E. JOHNSON, Potlatch, Idaho. The object here is to provide improvements whereby the operator is permitted to automatically control the head block knees wholly independent of the main set mechanism and with a view to move the head block knees toward or from the saw and to stop the knees accurately in the desired position.

CONTROLLING DEVICE.—R. V. INGLIS, Alpena, Mich. This invention relates to pulp or paper machines, and the object is to provide a device for use in controlling the flow of pulp into the paper machine with a view to supply the latter with the proper amount of pulp for the correct working of the machine and to insure a steady flow of the pulp without danger of clogging.

APPARATUS FOR REMOVING SAND AND OTHER FINE PARTICLES FROM COTTON OR OTHER MATERIALS.—F. B. CUMPSTON, Dallas, Texas. In the present patent the invention is an improvement in apparatus for use in removing sand or other fine particles from cotton or other material by air suction, and has in view an effective means to separate the particles from the inflowing current of air before the latter reaches the suction fan or air pump.

[illegible]TING RACK BED MOVEMENT.—C. [illegible], Plainfield, N. J. One of the objects in this improvement is to provide a device in which the reciprocating movement is effected by a driving gear which is located on a stationary shaft and which is rigidly secured thereto, the mechanism having far greater durability than in similar devices in which the driving gears are shifted with respect to the shaft.

### Prime Movers and Their Accessories.

STEAM TRAP.—G. KRISLING, Scranton, and J. D. BROWN, Dunmore, Pa. The invention relates to traps which are adapted to be introduced into steam distribution systems, for the purpose of collecting the condensed steam and discharging the water when a sufficient amount has been collected. An object is to provide a steam trap capable of forcing the water to an elevated position.

FRAMEWORK FOR TURBINES AND GENERATORS.—J. P. NICKOSOW, Evansville, Ind. The invention pertains to generators and to turbines for driving the same, the more particular purpose being to provide a suitable framework by aid of which the turbine, the generator and various parts associated with the same, are readily combined into a single machine of compact form.

IGNITER.—O. PEARSON, Worcester, Mass. In this engine the crude ore or other fuel is delivered directly to its interior and is vaporized by the heat remaining from the last prior explosion. Fuel is admitted simultaneously with the air, and the liquid strikes upon a heated baffle plate below the inlet plate. To facilitate the latter's heating and to avoid interference with the working of the valves, the plate is supported preferably upon the igniter.

### Railways and Their Accessories.

CAR FENDER.—J. L. SMITH, Rockville, Conn. The object of this inventor is to provide a car fender more especially designed for use on street cars and arranged to run very close to the rails, with a view to rapidly pick up persons or other obstacles in the path of the car. It is pivoted [illegible]

cross bar mounted on the car, and its front is provided with inclined guiding and supporting wheels engaging the inner side of the rails.

PASSENGER STRAP-HANGER.—W. B. McCarthy, Milford, Conn. To overcome many objections, the hanger is constructed of non absorbent material, as metal the same embodying a bar body having one or more advertising faces and provided with detachable end members, one of which is provided with suspending means and the other with a hand hold. A bar having one advertisement may be substituted for another, without discarding the entire hanger.

RAILOGRAPH.—J. H. Milligan, Baltimore, Md. The invention is in the nature of a pantograph adapted for application to the heads of railroad rails for ascertaining and recording their transverse contour or form upon a suitable scribing surface. This is performed by railroad companies at regular periods for the purpose of finding the wear and distortion of rails, and more particularly the heads and upper portions of the webs thereof.

CAR SEAL.—E. G. Gessaman, Chicago, Ill. The improvement refers to a seal to be used to secure the doors of a railway freight car or the like so that they may not be opened without becoming known. The aim is to provide a device cheaply manufactured and which may serve as a sure preventive of tampering without detection.

AUXILIARY CAR STEP.—W. O. Daly, Mobile, Ala. In the present patent the object of the inventor is the provision of an auxiliary car step which when not in use will be folded neatly and inconspicuously against the bottom of the fixed steps and which may be easily moved into operative position from the platform of the car.

MAIL-BAG CATCHER AND DELIVERER.—C. H. Anthony, St. James, Mn. The purpose here is to provide a device which will operate so as to take mail from a passing train, and deliver a bag of mail to the train simultaneously. The construction is such as to facilitate the delivering or catching of more than one bag of mail if desired.

SLIDING DOOR ASH PAN.—H. Alaman and W. McC. Lindley, Terre Haute, Ind. The improvement is in sliding door ash pans. The object of the invention is the provision of an ash pan especially adapted for use with locomotives, wherein the doors are slidably mounted and movable in the same horizontal plane, and operated in unison by a common operating means.

### Pertaining to Recreation.

AMUSEMENT FLYING MACHINE.—R. G. Inskeep, New York, N. Y. The invention is of that type in which a suitable machine containing pleasure seekers is traversed between a starting and a receiving station, being suspended by its own sustaining power intermediate the stations. The machine may be reversed. It may be given an upward throw as it leaves the starting rail. It is provided with means to traverse between a starting and a receiving station in either direction.

FISHING APPARATUS.—C. G. Johannsen, Chicago, Ill. This invention pertains to fishing and trapping and provides an apparatus for use in rowboats, rafts, power boats and the like and arranged to provide a means for suspending one or more fishing lines in the water at a safe striking distance from the boat and without unduly obstructing the interior of the boat.

GAME-COUNTER.—A. McKinney, Alpine, Texas. The intention in this instance is to provide a device for use in scoring the points as they are made and to keep a register of the number of games played, the returning of the counters proper to their original position after each game operating the game recording mechanism.

AMUSEMENT DEVICE.—G. A. Rosquist, New York, N. Y. The special purpose here is to so mount the cars or seats in respect to their axes, that they may have not only a rotating but a radial movement. The latter may be brought about by special mechanical means but preferably upon centrifugal force. The speed and time of radial movement are preferably controlled by varying the angle of the axis about which the car rotates, in respect to the main central axis.

### Pertaining to Vehicles.

VEHICLE-TIRE.—W. W. Scott, Hampton, Va. This invention refers to tires for emergency purposes. An object is to provide a tire which may be carried with the vehicle, and which may be slipped on in lieu of a damaged tire, so that the vehicle may be drawn back to the place where the damaged tire may be repaired.

### Designs.

DESIGN FOR A TRIMMING.—D. F. Weil, New York, N. Y. In this case the strip of trimming comprises an ornamental design wherein the chief figure represents dominoes stretched in oblique directions along the strip and between the spaces three stars are clustered in a triangle form.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th, 1909, or will be sent by mail on request.

(12219) C. F. L. says: 1. It is stated in textbooks of physics that of two colliding inelastic balls of masses $m_1$ and $m_2$ and velocities of $v_1$ and $v_2$ the velocity of their common mass after colliding will be represented by

$$V \text{ (common velocity)} = \frac{m_1 v_1 + m_2 v_2}{m_1 + m_2}$$

But the equation

$$(m_1 + m_2) v^2 = m_1 v_1^2 + m_2 v_2^2$$

does not hold in most cases upon giving the quantities $m_1$, $v_1$, etc., numerical values. In other words, there appears sometimes to be a gain of kinetic energy, which is contrary to the law of conservation of energy. It is asserted that if you transfer the momentum of a ball, weighing say 100 g to a ball weighing 200 g the heavier ball's velocity will be half that of the lighter the momentum of each being the same. But their kinetic energies will not be the same for (supposing velocity light ball 10 cm sec.) 100 x (10)² does not equal 200 x (5)², but is just twice as great. A. You do not give your address which is very essential according to the rules of our Notes and Queries column. Your queries would also come within what might be called "an examination paper." Fortunately your queries happen to be more or less of interest generally. Therefore we have taken the trouble to answer the same. We wish correspondents to understand however that we will not make a practice of answering miscellaneous queries of this nature which do not appear to be practical to themselves. It required over two hours to answer this query, and those who wish answers of this kind should expect to pay at least $4 for the same. Here follows the answer: When two bodies collide and after collision move on together their velocity after collision is determined as you state. It is a matter of momentum. The kinetic energy is a matter of mass and velocity and varies as the square of the velocity. It will be affected more by the change of velocity than the momentum is. 2. It is claimed that the vapor tension from a concave surface of a liquid is less than from a plane surface and that this is in some way connected with the phenomena of cohesion. Kindly explain. A. We cannot discuss the relation of shape of the surface of a liquid to its vapor pressure as we have not followed out any experimental work in that line and would suggest that you take up the matter with the original investigators whose opinion would be of value. 3. Why is the melting point of ice lowered by pressure? A. All liquids which expand upon freezing may be melted by compressing them in the solid condition into the volume which they had before they solidified. Liquids which contract upon freezing cannot be melted by compression since this only brings the molecules still nearer together. To melt them they should be expanded. If a liquid which expands upon freezing is prevented from expanding it cannot freeze since its molecules cannot move any farther apart, as they must do to turn into the solid form. 4. What are the properties of gas as liquid at the critical point as regards density, latent heat of vaporization, etc.? A. We are not able to find any figures as to the heat of vaporization for any substance at the critical temperature. The liquid expands as it is heated to the critical point. Its density is therefore diminished. Its vapor in the space above the liquid becomes more dense. At the critical point the two meet in density and an insensible change takes place. If more heat is applied the liquid disappears and the whole becomes a vapor. Duff Physics page 245 says: "It is idle to ask if the homogeneous fluid is a liquid or a gas. The continuity of the inclosed mass has never been broken. We can distinguish the two states only when the temperature is below the critical. You may find the density for several substances at the critical points given in the Smithsonian Physical Tables, page 200. 5. Is the phenomenon of a gas escaping through a small hole without friction to be regarded as a molar or molecular phenomenon? A. If the opening through which a gas is escaping is larger than a molecule, the escape of the gas is a phenomenon of a mass. 6. What is meant by the word entropy? A. In the Century Dictionary you may find the following definitions of Entropy: "As used by Clausius, the inventor of the word, and others it is that part of the energy of a system which cannot be converted into mechanical work without communication of heat to some other body or change of volume. As used by Tait and others it is the available energy or that part of the energy which is not included in the first definition." Clerk Maxwell defines as follows: "The entropy of a system is the mechanical work it can perform without communication of heat or alteration of its total volume, all transference of heat being performed by reversible engines." For fuller definition see Watson's Physics pp. 330-345. Price $1. 7. Would it be possible to hold a copper or silver coin suspended in air by means of a powerful magnet by virtue of eddy currents? A. Copper and silver are not attracted by a magnet in the slightest degree. 8. Why does the heat of vaporization increase as the temperature of the evaporating liquid is lowered? A. We are not able to explain why the heat of evaporation increases as the temperature of a liquid is lowered unless it is due to the fact that the liquid is further from its vapor condition at the lower temperature. 9. What is the best way to make a glass vessel chemically clean? A. Glass is cleaned by the action of nitric acid, potash and distilled water in succession.

(12220) T. H. calls our attention to an error which he made in Query 12217 in using the radius of the moon's orbit where he should have used the diameter as a basis of his calculation. This is true. We did not notice his error in reading his letter probably because we did not suppose any one would make such a mistake. If this correction is made the orbit of the moon becomes twice as long and the rest of the calculations can be corrected accordingly.

## NEW BOOKS, ETC.

FINANCIAL ADVERTISING. For Commercial and Savings Banks, Trust, Title Insurance, and Safe Deposit Companies, Investment Houses. By E. St. Elmo Lewis. Indianapolis: Levey Brothers. Pp. 992.

Mr. Lewis is peculiarly competent to write a book upon advertising for the simple reason that the better part of his life has been identified with advertising and particularly with the advertising of a certain adding machine which is much used in banking institutions. The work before us represents the fruits of wide experience in what the author calls financial advertising, and contains a fund of information which may well be applied to other kinds of publicity. Beginning with a brief history of advertising in which the town crier and the auctioneer and what might be called primitive advertising come in for their share of comment the author plunges into a second chapter on the banker's duty to the public a subject which may apparently have very little to do with advertising to the casual reader but which has a direct bearing upon banking publicity because of the intimate relation of banking to the people. Of wider use perhaps and therefore more valuable to the advertiser is the chapter on How to Reach the People. Here indeed Mr. Lewis is in his element for he gives many an excellent concrete example of what good advertising means how it is conceived and how a scheme is carried out. The essentials of good advertising are discussed under the various headings of Attracting the Attention, Awakening the Interest, and Creating Conviction, all of them decidedly essential as every up to date advertiser knows. The relative values of local newspapers, magazines, street car advertising, advertising novelties, booklets, folders, house organs, circular and form letters, etc., are thoroughly compared. We would commend particularly to Mr. Lewis's book as its essentially practical character. However the value of printing, the advertising manager and his work, the function of the publicity promoter, and the peculiarly special problems which confront savings banks, trust companies and stock brokers.

BROAD LINES IN SCIENCE TEACHING. Edited by F. Hodson. With an Introduction by M. E. Sadler. New York: The Macmillan Company, 1910. 267 pp. Price, $1.25.

If anyone needed evidence of the many-sided view of science in modern education he would surely find it in this admirable collection of essays edited by Mrs. F. Hodson and M. E. Sadler. In furtherance of the Editor's object to achieve through a variety of essays an adequate notion of the requirements within the latest case should be satisfied for boys in secondary schools, the various essayists who have contributed to this volume have carefully examined the claims of rival departments of scientific study and the various methods of teaching. The essays of which the book is comprised are the following: The Place of Science in the School Curriculum; The Scope of Nature-Study; The Teaching of Nature-Study; Biology in Schools; The Teaching of Hygiene; The Place of Hypotheses in Science Teaching; The Claims of Research Work and Examinations; School Mathematics in Relation to School Science; Co-ordination of Physics Teaching in School and College with Special Reference to Electricity and Magnetism; Geography; Science in the Teaching of History; Economic Science in Secondary Schools; Domestic Science; The Teaching of Chemistry in Technical Schools; How the School May Help Agriculture; Engineering; Science Teaching and the Training of the Affections; Science Teaching and a Child's Philosophy; The Present Condition of Physics Teaching in the United States; School Science in Germany; Some Practical Notes on the Planning of Science Laboratories.

THE PROLONGATION OF LIFE. Optimistic Studies. By Elie Metchnikoff. New York: G. P. Putnam's Sons, 1910. 343 pp. Price, $1.75 net.

Prof. Metchnikoff has been very much in the public eye of late years because of his bacteriological investigations of senility. As a result of his widespread teaching that the comparative shortness of human life is to be attributed largely to the enormous length of the human intestines and the putrefaction of food therein, the fermented milk industries have received a new impetus, for in the bacteria of fermented milk Prof. Metchnikoff finds those counteracting agents which stop putrefaction and thus lengthen human life. The theories advanced in the present volume do not differ from those advanced in his previous volume on the same subject. Metchnikoff offers for the treatment of old age a method of nutrition which he believes will diminish the danger to old persons from being attacked by those diseases to which they are especially liable. The book however is more than this. To a certain extent it presents Metchnikoff's views as to the conditions of life and the objects of existence. It is not a perfectly reasoned out philosophy nor is it based upon anything but purely physiological research. Yet it is a very real and very important contribution. The book is divided into the following parts: The Investigation of Old Age; Longevity in the Animal Kingdom; Investigations of Natural Death; Should We Try to Prolong Human Life? Psychical Rudiments in Man; Some Points in the History of Social Animals; Pessimism and Optimism; Goethe and Faust; Science and Morality. After reading this book one feels that cheerful optimism is one of Metchnikoff's temperamental qualities.

THREE RIVERS. The Hudson, The Potomac, The James. A Retrospect of Peace and War. By General Joseph P. Farley, U. S. A. New York and Washington: The Neale Publishing Company, 1910. Illustrated with ten sketches from nature by the author in water colors, reproduced in color. 8vo., cloth, handsome letterpress and binding. 277 pp. Price, $2 net.

The author of this work who though a Southern man by birth and affiliation fought for the Union in the civil war is known throughout the world as an ordnance expert and is one of the designers and constructors of the army 10-inch rifle, the largest type of gun extant to-day. After more than half a century of service in the army he writes this delightful retrospect of peace and war, a record in which anecdote, history, biography, observation and experience—books, battles, soldiers, picture, theories, men and things—are happily mingled. He has selected for his memory pictures the three rivers more intimately connected with his life. Along the banks of the James he recalls his boyhood and early manhood, many battles of his fighting days and the contest of the iron clads in Hampton Roads. On the Potomac he recalls many famous homes of famous families and recounts the inner history of such battles as Bull Run, Malvern Hill and Gettysburg. Finally he describes the old and the new West Point of the Hudson, this part of the book being replete with interesting biographical sketches relating to that historic center.

SCHLEY, SAMPSON AND CERVERA. By James Parker, formerly Lieutenant Commander U. S. N. New York and Washington: The Neale Publishing Company, 1910. 333 pp., 9 illustrations. Price, $2.

This work which is a review of the naval campaign of 1898 in pursuit and destruction of the Spanish fleet commanded by Rear Admiral Pascual Cervera is a contribution to the literature of the famous Sampson-Schley controversy. But it is much more than that, inasmuch as the author gives a very complete and connective account of the various naval activities both in Washington and on the high seas connected with the memorable Spanish war. While the author admits that it will be evident to the reader that his professional, legal, naval and personal judgments are favorable to Admiral Schley he has made it his aim to do full justice to every other officer concerned, being prompted to this by the fact that he still regards them as his professional brethren. He states that the book has been written without any consultation with Admiral Schley, who has never seen a line of it and does not know that it has been written. The work is published in the hope that a careful reading of the review will dispel all misunderstanding of that campaign, a misunderstanding which has persistently been promulgated in the effort to convey false impressions with regard to the principal actors in it. The work is so written that it should certainly put the reader in a position to judge for himself of the actual merit of the campaign. It is to be hoped however that with the publication of this work we have heard the last of this unfortunate controversy.

DIE HEISSDAMPF-SCHIFFSMASCHINE. Eine Sammlung von Erfahrungsangaben für die Berechnung der Abmessungen und des Dampfverbrauches, sowie des Kohlenverbrauches der Schiffmaschinen für Heissdampfbetrieb. Von Carl Fred Holmboe. Berlin: Wilhelm Ernst & Son, 1910. Price, $1.50.

STENOGRAPHER AND EMPLOYER. By Fessenden N. Chase. Portland, Me.: Press of Southworth Printing Company, 1909. 86 pp. Price, $1.

## INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending

April 5, 1910,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

### How Railway Traffic is Managed.

BY C. C. RECK.

Almost everybody knows something about railroad rules, but very few, unless holding or having held some railroad position, have a clear idea of just how many precautions are taken to prevent accident.

Whenever a big wreck occurs, through error in train orders, oversight of a telegraph operator, engineer, conductor, or flagman, the newspapers usually give one cause and blame one person, when more than likely two or three are equally to blame.

The rules of course vary to some extent on the different systems, but those explained in this article are near enough standard to give the reader a clear insight into just how many things must go wrong before a collision can occur. The road in mind has part single and part double track, uses the telegraphic block system on the single track and automatic electric block on the double track. The rule book, which is the railroad man's Bible, is a little book not much larger than a post card, one-quarter inch thick, and contains only 120 pages. All changes and special instructions are issued in the employees' time table, which contains the schedule time of every train at all stations. This time table divides the trains into four classes, passenger trains being first class, time freights second class, and so on. It also gives east bound trains right over west-bound trains of the same or an inferior class, so an east bound first-class train has right over all trains and pays no attention to any schedule but its own while a west-bound first-class train is superior to everything except a first-class train east-bound, but has to take care not to encroach on the schedule time of any first-class east-bound train. A poor fourth-class train west-bound is inferior to everything, and when on consulting his watch and time table the conductor finds some higher class train nearly due, it has to dodge into a side track, allowing a first or second-class train to run ahead, or to meet a first, second third, or fourth-class train. Now, if trains never got late, watches never went wrong, or train crews never looked at their own or other schedules wrong trains could move along just on their time-table rights as their schedules are so figured that they meet, pass, and are passed at certain stations and certain times. But some things will go wrong. So as an additional precaution the dispatcher issues train orders telling them where to meet and pass, giving inferior trains orders that some superior train is running late where to run slow on account of bad track reported by track walkers and in every way trying to save delay and insure safety.

These train orders are sent to all trains and stations concerned at the same time, and are not delivered to any train until all copies have been correctly repeated. When a train order increases the time-table rights of a train, it may be handed up to the moving train, but when it restricts these rights, the train crew has to stop and sign for the order. The telegraph operator is required to set all block and train-order signals at danger, and so notify the dispatcher before he copies a train order, and must not change these signals until the order is delivered, or if the order is for trains to meet at his station, his danger signal must remain displayed until the meet has been accomplished.

In addition to running by train orders and schedule, a block system is operated independently. At every station is one tall pole, called a semaphore, on which signals are displayed. The space between two of these semaphores, usually three or four miles, is called a "block." Now, under absolute block rules, no two trains can occupy the same block at one time. The block signals on the semaphores stand at danger all the time, and are never clear except when held in this position by the operator. A train before

proceeding is required to see this signal change from danger to clear

At all stations a record is kept showing the departing time of every train at this station and at the next station east and west. Supposing a west-bound train to be approaching a station semaphore. The telegraph operator, if he has no orders on hand for this train to meet anything at his station, consults his block record, and if the block west is clear he calls up the station west, and obtains permission to let a train in the block. He then pulls his block signal clear and holds it in this position until the train is by, immediately reporting it to both block stations and the dispatcher.

If a train from any cause has to stop between stations or finds itself on the schedule time of a superior train it has to flag, putting down torpedoes and sending a man with a red flag ahead and back notwithstanding the knowledge that the telegraph operator will not let another train enter the block until it is clear.

Now, on double track things are very much simplified, as all trains going in one direction move on the same track, and only have to take siding to allow a train of higher class to run ahead. This allows the use of automatic electric block signals placed at intervals of about a mile, all signals being on the right hand side of the track which they govern. At every one of these signals the joints between the rails are insulated, thus cutting the tracks up into blocks between the signals. These signals are so wired that when a train approaches one of them, if the block ahead is clear, the circuit will be completed from one rail to the rail on opposite side of track through the wheels of the train, causing the signal to come clear, in which position it stands until the engine passes it. If one of these signals fails, the train is required to wait a minute or two long enough to allow a preceding train to clear the block or to flag, and then proceed with caution to the next signal, reporting the failure at first office.

These automatic signals work over two thousand times to one failure, and are so constructed that a failure leaves the signal at the danger position.

### Estimation of the Working Capacity of a Man Before and After an Accident.

The problem of determining the working capacity of the victim of an accident is divided into two parts. It is necessary to establish, first, the condition in which the accident has left the various organs and functions of the body, and secondly, the effects of the consequences of the accident upon the power to work, either at the victim's previous occupation, if he is able to continue it, or at such other occupations as he may be able to carry on. Dr. Imbert in a recent article criticises the methods generally employed for the solution of this problem. The attendant physicians and the medical experts give only their personal opinions, instead of employing the exact methods of examination which are used in physiological laboratories. Thus in many cases, in which the statements of the victim appear false or exaggerated, the truth could easily be ascertained by the use of X rays or by the electric exploration of the nerves and muscles. Dr. Imbert describes various researches which he has made in the physiological study of certain occupations. He thinks that it is possible to arrange a mass of useful data in a form in which they would be available for the decision of individual cases.

That apparently most remote of the sciences from the exactness of physical laws, economics, has been brought under the treatment of mathematics, not only by statistical methods, but by methods of the calculus. The distinguished mathematician and economist Cournot applied to the theory of wealth methods like those used in mechanics to treat of equilibria, so that very complicated economic principles were amenable to treatment by symbols.

## THE ANNUAL SMALL HOUSE NUMBER

OF

# American Homes and Gardens

THE May Number of American Homes and Gardens will be devoted to the small house, its building, its decoration and its furnishing. This issue will contain a vast amount of information for the prospective home builder. Special attention will be given to the inexpensive small house, which is the most numerously erected dwelling in America and the type of house that at once excites the widest interest and offers the richest field for suggestive helpfulness.

Various departments conducted by specialists add greatly to the value of this number and the aim has been to bring out the charm of the simple beautiful things which contribute to domestic comfort and happiness, solely for the purpose of solving the problems which confront the house-owner but which cannot be explained without the assistance of a competent expert. It will tell him how to select the country site, how to place the house upon it, the style of architecture in which the house should be designed, how the various rooms of the house should be planned, the material of which it may be built, the kind of plumbing fixtures to be used, the choice of hangings for the walls, doors and windows, appropriate furniture for the various rooms of the house, and how to lay out the grounds about the house as well as to the planting of them. Beside these departments, the magazine will contain a host of articles that must inevitably stimulate the desire for home improvement.

**THE MODERATE HOUSE FROM THE ATLANTIC TO THE PACIFIC.**—This is an article by Francis Durando Nichols, treating of the modern house as seen in the various parts of the country and it is illustrated by photographic views of the exterior and interior of the houses as well as the plans of five houses which represent the best type of modern house built at five different points.

**HOW TO BUILD A PERGOLA AND A GARDEN SEAT.** A. Russell Bond tells in an illustrated article how it is possible for an amateur to build a pergola and a garden seat for a small garden. He shows photographic views of the pergola and a garden seat and also working drawings which may be used in carrying out the subject to accurate detail. Very few understand the significance in furnishing a colonial house, in its truest sense. Mary Livingston, who has made a special study of this subject, presents an article on how to furnish the various rooms of a colonial house, including the hall, drawing room, library, dining room, and bed rooms, which is profusely illustrated with views showing the best examples.

**THE SMALL KITCHEN OF TO DAY.**—There is no part of the house which receives so little attention and yet requires so much, as the kitchen. Mr. Robert Spencer, Jr., has prepared an interesting article on its planning and equipment, which is well illustrated with numerous plans showing its proper relation with the other rooms of the house. All good housekeepers realize the importance of this subject, and no one is better qualified to give such information than Mr. Spencer, who has made a special study of the kitchen and its dependencies.

**THE OUT-OF-DOOR LIVING ROOM.**—Now that we are coming to the warm season of the year our thoughts dwell upon getting out of doors, and there is no more important feature of a house which should receive proper consideration than the living porch. Mr. John A. Gade has prepared an article treating upon this timely subject, which is illustrated, showing the various ways by which a porch may be furnished and inclosed with screens in summer and glass in winter.

**SOME CALIFORNIA BUNGALOWS.**—The California bungalow is always interesting and Helen Lukens Gaut has prepared an article on this subject accompanied by illustrations of eighteen bungalows. The bungalow is always of concern to those who want to live out of town during the summer months, and this article tells one how it is possible to obtain one at so low a cost as $150.

**PLANNING THE SMALL GARDEN.**—The garden is a frame for the house picture and success in its treatment means that each tree and shrub should be properly placed as well as properly grown. Loring Underwood, the well-known author, tells, in a very pleasing way, how it is possible to obtain this garden picture. The article is illustrated with drawings showing how the garden is planned and photographic views showing how it has been developed.

**DECORATIONS AND FURNISHINGS FOR THE HOME.**—Alice M. Kellogg presents her third paper, which is devoted to wall papers and curtains. This article is illustrated with photographic views showing the combination of wall papers and curtains of the same design and pattern for the use at windows and also for the spreads to be used upon the beds and the couch of the sleeping room.

**AUTOMOBILING.**—The automobile has become a necessity for the country house of today and Stanley Yale Beach, the Automobile Editor of the SCIENTIFIC AMERICAN, tells in a practical way how it is possible for a man to have and maintain a small motor car. The article is illustrated, and shows automobiles costing from $485 to $1,000.

**POTTERY MAKING FOR THE AMATEUR.**—Everyone is interested in pottery making, especially the kind of pottery making which can be done by the amateur. Mabel Tuke Priestman presents in an illustrated article views that show some of the most beautifully made pottery of America.

**FURNITURE FOR THE ARTS AND CRAFTS HOUSE.**—Furnishing the arts and crafts house is a subject which is very intimately presented by Edith Haviland. Miss Haviland takes one through the house, and shows the proper furniture and treatment for the various rooms.

**THE USE OF CEMENT IN THE BUILDING OF THE SUBURBAN HOUSE AND GARAGE.**—Mr. Robert W. Gardner, the well known architect, who has made a special study of the use of cement, has prepared a very excellent article on the subject, which is profusely illustrated with many fine engravings, showing the various uses that can be made of cement in the building of the suburban house and garage.

**GARDEN NOTES.**—Charles Downing Lay describes in his department how to lay out and plant a lawn, the kind of trees and shrubs to avoid in planting, and a vast amount of other information that will be helpful to those who desire to improve their home grounds.

**The price will be 50 cents. Those now subscribing for American Homes and Gardens will receive it at the regular rate. Subscription price $3.00 a year.**

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO. Inc.

## PATENTS FOR SALE

FOR SALE. U. S. patent automatic time cut off for individual electric lights. Needed wherever electricity is used for lighting. Will submit particulars and sample to those interested. Paul Dixon, 67 Whitehall St., Atlanta, Ga.

**Inquiry No. 8918.**—For manufacturers of "Wydt's Electro Catalytic Sparking Plug."

## HELP WANTED

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres. The Nat'l Co-op. Real Estate Co., Suite 378, Marden Building, Washington, D. C.

**Inquiry No. 8987.** Wanted the manufacturers of the Van Winkle Woods & Sons and the Waber power sanders.

MECHANICAL SUPERINTENDENT to take charge of large machine shop. Apply stating experience and salary expected. Superintendent, Box 773, N. Y.

**Inquiry No. 9011.** For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

EXPERIMENTAL ENGINEER wanted by a large manufacturing concern having technical and practical knowledge of mechanics and preferably chemistry as well. Must possess special aptitude for this character of work. Address in confidence with full particulars including salary expected. Business Service Co., 305 Broadway, New York.

**Inquiry No. 9016.** Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

**Inquiry No. 9023.** Wanted to buy silk machines from re-reeling, twisting, doubling to the final process of making it into clothes.

## SALE AND EXCHANGE

FOR SALE. Engine lathe. Our regular $75.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $42.50. L. F. Grammes & Sons, Allentown, Pa.

**Inquiry No. 9030.** Wanted catalogues and all information on machinery for braiding straw in manufacturing straw hats.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

**Inquiry No. 9038.** Wanted the address of the Chipman Electric Purifying Co.

**Inquiry No. 9042.** Wanted the address of Farney Safety Razor Co.

**Inquiry No. 9052.**—Wanted address of firms who install plants to manufacture nitrogen.

**Inquiry No. 9053.** Wanted address of parties interested in Gas Cleaning Machines.

**Inquiry No. 9060.** Wanted to buy machinery to manufacture seed corn racks.

**Inquiry No. 9066.** Wanted complete outfit for export for making rice flakes and wheat flakes.

**Inquiry No. 9069.**—For the address of firm making chain cloth, something like ladies' purses are made of.

**Inquiry No. 9071.**—Wanted the address of parties making moulds for large concrete vases for flower pots.

**Inquiry No. 9073.**—Wanted, machinery to manufacture cocoanut oil; also the crude material.

**Inquiry No. 9074.** Wanted to buy old model locomotives or steamboats, such as were exhibited with nickel-in-the-slot attachments in ferry houses, etc.

**Inquiry No. 9075.** Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

**Inquiry No. 9076.**—Wanted the address of parties in Canada who could make a safety razor.

**Inquiry No. 9077.** Wanted the address of manufacturers that make small articles of wood, such as checker boards, etc.

**Inquiry No. 9078.** Wanted the address of manufacturers of sewer pipe, made of fiber and asphaltum, suitable for laboratory use.

**Inquiry No. 9079.** Wanted, parties to make a special tin plate rolled for "angle bars" in large quantities.

**Inquiry No. 9080.** Wanted the address of parties manufacturing paste-making machinery.

**Inquiry No. 9083.** Wanted the address of firms manufacturing small beer brewing plants, from 25 to 100 gallons a day.

**Inquiry No. 9084.**—Wanted, the address of manufacturers of Irwin portable bath tubs.

**Inquiry No. 9085.**—Wanted to buy longitudinal hollow perforated tubing.

**Inquiry No. 9086.**—Wanted to buy a pine wood peeler.

**Inquiry No. 9087.** Wanted a machine for hardening hack saw blades; also a machine for setting same when they have been toothed.

**Inquiry No. 9090.** Wanted manufacturers of shoe oiler and supporters supplies; also patent adjustable bachelor buttons.

**Inquiry No. 9092.** Wanted the address of some firms who manufacture permanent lamp wicks.

**Inquiry No. 9091.** Wanted address of The Thomas Arithmometer Company; also Burkhart Arithmometer Company.

**Inquiry No. 9095.**—Wanted, name and address of the manufacturer of the duplex revolving pencil sharpener.

**Inquiry No. 9096.**—Wanted the address of manufacturers of spiral welded pipes, possessing great strength.

**Inquiry No. 9097.**—Wanted address of makers of impulse water wheels.

**Inquiry No. 9098.** Wanted name and address of the manufacturers of the combiner.

**Inquiry No. 9099.**—Wanted address of manufacturers of machinery for making wire cables.

**Inquiry No. 9101.** Wanted addresses of manufacturers of a dip or magnetic needle, for exploring for iron ore.

**Inquiry No. 9104.**—Wanted addresses of manufacturers under the name of A. O. Co. Standard.

**Inquiry No. 9106.**—Wanted addresses of cotton dealers who can furnish cotton material for manufacturing envelopes.

**Inquiry No. 9107.**—Wanted addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

**Inquiry No. 9109.**—Wanted addresses of the manufacturers of the Dim Desk Clock.

**Inquiry No. 9110.**—Wanted to buy machinery for reducing old tin cans, so that they may become a source of revenue.

**Inquiry No. 9112.**—Wanted sample small dry vacuum pump about 6-inch diameter cylinder inside, high temperature metal packing.

**Inquiry No. 9113.**—Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

**Inquiry No. 9114.** Wanted name and address of manufacturer of the Auto Lantern Globe. Fits all lanterns.

**Inquiry No. 9115.**—Wanted a machine for making pen nibs similar to Wm. Mitchell's G. & J. nibs and Waverly nibs.

**Inquiry No. 9117.**—Wanted names and addresses of the manufacturers of pedometers.

**Inquiry No. 9118.**—Wanted a muffler for a gasoline engine built upon the principle of the Maxim silencer recently brought out for use on rifles.

**Inquiry No. 9119.** Wanted, name and address of the manufacturer of Bezlin bullet proof cloth.

**Inquiry No. 9120.**—Wanted the address of the Ideal Fuel Feeder Co.

**Inquiry No. 9121.**—Wanted manufacturers of cut stencils for fancy work, sofa pillows, etc., and oil colors and brushes for same.

**Inquiry No. 9122.**—Wanted, manufacturers of ditching machines used for tiledrains operated by horse power.

**Inquiry No. 9124.** Wanted name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

**Inquiry No. 9125.**—Wanted name and address of the Just Hatmaker machine for manufacturing milk powder.

**Inquiry No. 9127.**—Wanted address of L. Dagmigny, manufacturer of a family ice machine for $30.00.

**Inquiry No. 9131.**—Wanted information as to how or where I could get a sample of tin ore.

**Inquiry No. 9132.** Wanted, manufacturers of a gasoline traction engine with a hoisting attachment; in other words, the machine will be used as a portable stump puller to pull sassafras roots, used in making oil of sassafras.

**Inquiry No. 9133.**—Wanted, manufacturers of floss candy machines.

**Inquiry No. 9134.**—Wanted, a small hydraulic motor capable of giving about one horse power with a water power of 25 lbs. per square inch.

**Inquiry No. 9135.** Wanted, name and address of manufacturers of the Parshall Compressed Air Ice Machine.

**Inquiry No. 9136.**—Wanted the name and address of a skunk raising farm.

**Inquiry No. 9137.**—Wanted, a device that will braid leather strips for horse whips.

**Inquiry No. 9138.**—Wanted the address of manufacturers of machines capable of forming a number (12 or more) of pieces of paste about 30 mm. x 12 mm. x 6 mm. made of lead oxide and sulphuric acid, and placing them into a frame having a separate compartment for each piece, the space between each piece and the next being all round 4 mm. The process would be somewhat similar to biscuit making.

**Inquiry No. 9139.** Wanted the name and address of some manufacturer of a coffee mill run by water motor.

**Inquiry No. 9140.**—Wanted manufacturers of disc records for gramaphones that use a sapphire point instead of a steel needle.

**Inquiry No. 9141.**—Wanted a boat like a rowboat, worked by levers in place of oars, which by a series of pulleys attached operates a propeller, the steering device is managed with the feet.

**Inquiry No. 9142.**—Wanted, an appliance used in ice chests to make ice last longer.

# Instructive Scientific Papers

## ON TIMELY TOPICS

**Price 10 Cents each by mail**

**ARTIFICIAL STONE.** By L. P. Ford. A paper of immense practical value to the architect and builder. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

**THE SHRINKAGE AND WARPING OF TIMBER.** By Harold Busbridge. An excellent presentation of modern views; fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

**CONSTRUCTION OF AN INDICATING OR RECORDING TIN PLATE ANEROID BAROMETER.** By N. Monroe Hopkins. Fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

**DIRECT-VISION SPECTROSCOPES.** By T. H. Blakesley, M.A. An admirably written, instructive and copiously illustrated article. SCIENTIFIC AMERICAN SUPPLEMENT No. 1493.

**HOME MADE DYNAMOS.** SCIENTIFIC AMERICAN SUPPLEMENTS 161 and 600 contain excellent articles with full drawings.

**PLATING DYNAMOS.** SCIENTIFIC AMERICAN SUPPLEMENTS 720 and 793 describe their construction so clearly that any amateur can make them.

**DYNAMO AND MOTOR COMBINED.** Fully described and illustrated in SCIENTIFIC AMERICAN SUPPLEMENTS 844 and 865. The machines can be run either as dynamos or motors.

**ELECTRICAL MOTORS.** Their Construction at Home. SCIENTIFIC AMERICAN SUPPLEMENTS 759, 761, 767, 641.

**Price 10 Cents each, by mail**

NEW YORK SATURDAY, APRIL 23rd, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic the contributions will receive special attention. Accepted articles will be paid for at regular space rates

## TRUE WAY TO PREVENT RAILWAY ACCIDENTS.

It is well understood among railroad officials that the most fruitful cause of railroad accidents in this country is to be found in the lax sense of discipline among the employees Presumptive proof of this is found in the fact that, although our leading railroads have been equipped with a block signal system and other safety appliances, which are generally equal and in some cases superior to those on European railroads, the number of accidents in proportion to the number of people carried continues to be larger in this country We therefore note with much satisfaction that the Chicago and Northwestern Railway has taken a step in the right direction by appointing an official whose chief duties will be to make a study of railway accidents, and by a system of education and strict enforcement of discipline, endeavor to eliminate the most fruitful cause of injuries to passengers and damages to freight Opportunity was recently taken of the reorganization of the company's claim department, to relieve the claim agent of much of the detail of his work and allow him to make a careful study of the causes of all accidents in the handling of passengers and freight It will be his duty to bring about a more thorough co-operation and a higher state of discipline among the various employees, upon whose fulfillment of their duties the safe operation of the trains immediately depends The scheme is a most excellent one, and we believe that its results will be so satisfactory as to lead to similar arrangements on at least the more important railroads of the country

## AN EPOCH-MAKING EXPERIMENT.

At the last meeting of the Institution of Naval Architects, a paper was read by the Hon C A Parsons which created a profound impression among the British naval architects and shipbuilders It was described by Prof J A Ewing of Cambridge University as epoch making", and the announcements which it contained must be considered as second only in importance to those which were made by Mr Parsons after the successful trial of his first turbine driven steamer, Turbinia '

Mr Parsons's paper which was entitled The Application of the Marine Steam Turbine and Mechanical Gearing to Merchant Ships,' described the successful application of a combined steam turbine and reduction gear to a slow speed merchant steamer, the "Vespasian The Vespasian' is a small cargo steamer of less than a thousand tons displacement, which in her original condition was driven by reciprocating engines which were sufficiently up-to-date to be considered as representative of the average engine-room equipment of the modern tramp steamer To make certain that the comparison would be trustworthy, and equally favorable both to the reciprocating and the turbine engine the reciprocating engines were thoroughly overhauled and put in first-class condition The ship was then taken to sea and put through a course of trials in which complete data relating to draft weather water and coal consumption etc, were collected The vessel was then returned to the yard the reciprocating engines were removed and a fast-running steam turbine with a 1 to 40 reduction gear was installed, the propeller used with the reciprocating engine being left untouched The reduction gear consisted of pinions on the high-pressure and low pressure turbine shafts and a large spur wheel on the propeller shaft The gears were of cast iron and the whole was mounted in plain bearings without the use of any special adjustment devices. The "Vespasian" was then taken to sea, and put through a similar course of trials to those which were run with the reciprocating engines Except for the substitution of turbines for reciprocating engines, the ship with respect to draft, boilers, and propeller was in exactly the same condition as in the first trials.

When the results came to be worked up, it was found that with seventy revolutions of the propeller, there was a net gain of from 15 to 16 per cent when steam for all purposes was considered, and of from 18 to 19 per cent for the propelling engines alone Translated into terms of boiler power, this means that one boiler out of every six in the slow cargo boat can be dispensed with

Speaking of the important question of the strength of the mechanical gearing Mr Parsons stated that as the 'Vespasian had been taken out in a heavy sea without experiencing any trouble with the reduction gear, it was probable that the gear would stand anything that the shaft would stand In the discussion of the paper various shipbuilders referred to the long-standing prejudice against mechanical gearing, and it was the general opinion that its rapid wear was due to the imperfections of manufacture which characterized machine work in the early days of the steamship, when gearing was used for speeding up the propeller just as to-day it is being used for speeding down The early mechanical gearing, moreover, because of its imperfection, was very noisy, but it was agreed that the almost perfect gear cutting which can be done to-day will practically eliminate the noise, particularly if the gear be suitably inclosed and sound-deadened

Mr Westinghouse recently proved, in the remarkable tests with a 6,000-horse power reduction gear which were carried out at the Pittsburg shops, that by the use of helical gearing, which is the type that was used on the "Vespasian," it is possible to transmit large horse-powers with an inappreciable amount of wear and with an efficiency of over 98 per cent, which is about the same efficiency as was secured by Mr Parsons

Now the vast importance of these 'Vespasian' trials will be appreciated, when we bear in mind that about two-thirds of the steam merchant marine of the world is of the slow cargo-carrying type, for which the steam turbine, because of its high speed of revolution, has been found to be unsuitable Moreover, the 'Vespasia was the first vessel to be fitted with the new system and it is reasonable to conclude that with its further application to cargo steamers, an average *economy of at least 20 per cent will be guaranteed* on the engine and 17 per cent on engine and auxiliaries, or as Prof Ewing put it, there will be a saving of one boiler in six on the whole equipment.

Furthermore, not only will there be economy at the coal pile but the reduction in weights will make possible a considerable increase in the cargo-carrying capacity In this connection, it should be noted that the United States Navy Department has authorized the installation of Westinghouse turbines with Melville and McAlpine gears in the new fleet collier No. 8, which is being built at Sparrows Point, Maryland The space and weight saved by the use of this apparatus as compared with the reciprocating engines originally contemplated for this vessel, will enable it to carry about 200 tons more coal, and it is believed that the economy in coal consumption will be such that the saving thereby effected will add another 200 tons to the net carrying capacity of the collier

## WATERWAY DEVELOPMENT IN EUROPE AND THE UNITED STATES.

We note that a contemporary sounds a word of warning against precipitate action in the wholesale development of the waterways of the United States, by drawing attention to a document issued by the British Royal Commission on canals and waterways, which it considers to be worthy of serious study on this side of the Atlantic The report deals with the waterways of Belgium, France Germany, and Holland, and our contemporary advises that it be studied in connection with the recent report of the army engineers on the proposed 14-foot waterway from the Lakes to the Gulf It is claimed that the Royal Commission report strongly sustains the contention of the army engineers that the Mississippi and its tributaries, with 14 000 miles of navigable waters, as developed and maintained by the government, furnish as good an inland waterway system as any in Europe

In France the waterways that are used considerably include a total of about 7,500 miles of rivers and canals, and of this 1,306 miles of rivers and 1,671 miles of canals have been deepened to a minimum depth of 6 6 and to a maximum depth of 8,5 feet, the bulk of the traffic being carried on water varying from 5 feet in depth down to 1 5 feet.

In Germany there are 8,590 miles of waterways, the depth of which in the rivers varies from 3 to 6 feet, while on the lower sections of the larger rivers the depth becomes from 8 to 10 feet. The depths of the canalized rivers are from 2.6 to 7 5 feet, and of the canals from 4 to 10 feet, from 4 to 6 feet being the most common Comparing these figures with those of the Mississippi, we find that, even in the low-water season, boats of 25 to 30 feet draft may be sent from the Gulf of Mexico 270 miles to New Orleans, Baton Rouge, and Bayou Sara. Boats of 9-foot draft may travel 840 miles farther to Cairo, those of 8-foot draft may pass from Cairo 182 miles to St. Louis; while those drawing 4½ feet may pass up the Mississippi, Illinois River, and Illinois State canals, a further distance of 365 miles to Chicago The Ohio has a depth of 9 feet from Cairo to Pittsburg, a distance of 1 000 miles.

Now, since the Mississippi and its tributaries actually constitute a better waterway system than any in Europe, the question is asked, Why is the river and canal traffic in Europe growing faster than the railroad traffic, while in the United States railroad traffic is rapidly increasing, and river and canal traffic falling off? One important reason is that both the municipal and private interests in Europe have provided the waterways with good terminals, and boats and barges have been developed which are specially adapted to river and canal traffic Here, practically nothing of the kind has been done

As an offset to these conditions, the advocates of larger waterway development are in favor of the construction of much deeper waterways than any in Europe, deep enough to allow lake and ocean-going vessels to pass through. When the government investigated this subject for the State of New York, the conclusion was reached that the cost of transporting grain by the typical lake freighter on a deep-water canal would be 38 per cent greater than by a towboat and barges on a barge canal, and it was this conclusion that led the State of New York to abandon the idea of a 20-foot canal

Our contemporary is of the opinion that it would be the very height of folly for the government of the United States, under present transportation and commercial conditions to spend hundreds of millions on the development of inland waterways believing that the only way by which considerable commerce could be diverted to the present or proposed waterways would be to compel the competing railroads to raise their existing rates on low-grade commodities and refrain from making reductions In France the government compels the railways to keep their rates at least 20 per cent higher than the rates on the competing waterways, this practice according to the report of the Royal Commission, being based on the opinion that waterways, because of the longer duration of transport, are not able to compete at equal rates with the railroads

## OSMOTIC PRESSURE AND CURRENTS.

It is known that a current can be generated by forcing a liquid through a porous diaphragm or filter, but such currents were too small to be of practical value The matter has been taken up by a German scientist B Schwerin He claims to have obtained remarkable results in current production A liquid circulates in a tube of large diameter and at a high pressure Inside the tube is placed a filter through which the liquid passes, consisting of a certain thickness of a porous substance contained between two sheets of wire gauze The current is taken from each of the sheets by a wire To produce a current we must have the proper liquid and the filter must be specially made Adding suitable salts to water we find a high value for the current At the same time the diaphragm must be made of matter in an impalpable powder to be effective, so as to reduce the size of the pores As an example he uses a pressure of 5 atmospheres for the liquid, and a layer of finely powdered carbon ½ inch thick with a surface of 32 square inches, the internal resistance being 1 000 ohms when distilled water is used But a small current is now produced, but when we add ammonia to the water the current is increased ten times and the electromotive force twice, therefore we have 20 times the energy by using ammonia The best results are given by fine quartz powder and the use of a much higher pressure At 30 atmospheres we have as high as 32 volts and 0 8 ampere, or 2.6 watts, which is a very good result. The energy seems to vary as the square of the pressure, and at higher pressures we could obtain large currents. When the pores are finer the flow is lessened, but the energy is about the same. The liquid is best sent in a closed circuit of piping

## HALLEY'S COMET

The first observations of the comet in the morning sky show that it is disappointingly faint. Its intrinsic light has evidently not increased as rapidly as in the case of some other comets. Unless there is a change in this respect, it will be far from conspicuous to the naked eye until the latter part of May, and those who wish to see it in the morning sky will do well to use field glasses, and to look for a much fainter object, with far less of a tail, than our front page illustration of last week showed.

## ENGINEERING.

**The Pennsylvania Railroad** last week operated the first electric train through the tunnels under Manhattan Island and the East River. The train, made up of six construction cars and an electric locomotive, ran from the station in New York to the Thompson Avenue viaduct in Sunnyside yard, Long Island City.

**An important** link in the proposed waterway from the Lakes to the Gulf must be eliminated from consideration of that scheme, at least for the present. The section referred to is known as the Illinois River Deep Waterway, for which it was proposed that the State should spend $20,000,000, in the extension of the Chicago drainage canal down the valley of the Illinois River. The bills proposing to proceed with the construction were defeated in a special session of the Illinois Legislature, which adjourned last month.

**The city** of Seattle is doing some exceptionally heavy grading in the reduction of the steeper hills in that city. This grading, which has always been going on intermittently, has recently been undertaken on an ambitious scale, and under the present scheme over fourteen million cubic yards have been removed. When the plan is completed, the total will have reached thirty-four million cubic yards. The work is being done by the hydraulic sluicing method, and the present project covers an area of forty-three city blocks.

**The Great Western Railway** in England is installing a compact railway ticket printing machine. When a ticket for a certain station is required, the clerk touches an indicator which carries the name of the station, slips a blank into a slot, turns a handle, and the completed ticket drops out. At the same time a record of the sale is printed on a continuous strip of paper, together with the fare and all information required for bookkeeping. When the clerk goes off duty, he simply has to total up the continuous strip of paper and count his cash.

**It is well** understood among naval men that the speed of a vessel is affected by the depth of the water not merely in shoal places, but in the deeper waterways. With a view to determining what effect different depths of water have on speed, the Board of Inspection and Survey has arranged that the standardization trials of three vessels shall be made over three different courses. The battleship "Michigan" and the destroyers "Reid" and "Flusser" will have their trials over three measured mile courses, one at Rockland, Maine, another at Cape Cod, and the third in Delaware Bay.

**The Mallet** articulated compound locomotive continues to grow in favor, the reports from locomotives of this type which have been some time in service being in general very favorable. The New York Central system has recently put its first Mallet compound in service on the Boston & Albany line. The present class of heavy freight engine on that road has a maximum tractive power of 26 tons, whereas the Mallet, when working compound, has 33 tons, and when working simply 40 tons tractive power. The success of this type in freight service is undisputed. What results it will give in fast passenger service time will tell. The operation of the powerful express Mallet on the Santa Fé road will be watched with great interest.

**Advices from Washington** state that the chief of the Bureau of Navigation of the Navy, the aid for operations, and the aid for personnel, are mapping out another extended cruise for the Atlantic fleet. At present the scheme proposes a naval review at Hampton Roads, followed by the departure of sixteen ships in four divisions for Gibraltar, where the divisions will separate and visit the leading ports on the Mediterranean. It is possible, though not decided, that the fleet will proceed thence through the Suez Canal to the Philippines and San Francisco, returning home by the Straits of Magellan. The fleet will include the four new dreadnoughts, "Delaware," "North Dakota," "Michigan," and "South Carolina," and the "New Hampshire," "Mississippi," and "Idaho," seven of our latest battleships, which were not present on the former cruise.

**We are indebted** to Mr. Frank G. Taylor for the description of the new dam with which it is proposed to replace the wrecked structure across the Colorado River, which was carried away at Austin, Texas. The dam, which will be constructed of reinforced concrete, will rise 65 feet above low water and extend for 1,096 feet in length. The portion of the old dam which was not carried away will be incorporated in the new structure. It will be supplemented by a reinforced concrete addition, which will raise its crest eleven feet higher than the old dam. To prevent the recurrence of the seepage through the fissured rock, which was so disastrous to the old structure, curtain walls two feet thick are carried down thirty feet below water, and at the bottom of the trenches holes are drilled five feet apart to a depth of thirty-five feet, into which liquid cement grout will be pumped at a pressure of 150 pounds per square inch, thus filling the crevices.

## ELECTRICITY.

**Russia** is becoming interested in hydro-electric power plants, and is examining into the matter of electrifying suburban divisions of its State railroads. An investigation is being made of our high-tension transmission systems, and it is probable that a new field will be opened for American engineers.

**An electric lighting** plant in Nebraska is manufacturing ice as a by-product. The exhaust steam of the plant, which would otherwise go to waste, is utilized in the ammonia absorption process of ice manufacture and also for distilling water from which the ice is made. This venture, we are informed, has proved a very profitable one for the lighting company, and might be copied to advantage by other plants similarly situated.

**A new system** of treating eggs so as to prevent them from growing stale when in cold storage has been discovered in Rochester. This consists in subjecting the eggs to an electrical current. The theory is that eggs when placed in storage are alive and are gradually frozen to death, whereas if the life is destroyed by an electrical current before they are placed in storage they do not taste stale, even when kept on ice for a long period of time.

**In an address** recently made by Prof. John W. Whitehead of Johns Hopkins University it was pointed out that out of the 220,000 miles of railroad in this country, only a thousand miles have as yet been electrified. He called attention to the fact that the electrification of the elevated railroads in New York resulted in increasing the capacity of the roads fifty per cent. To be sure, the questions of electrifying suburban, express and freight service require separate consideration, but Prof. Whitehead shows that in each case electrification is possible and often preferable.

**Tungsten filaments** are commonly made by mixing the metal in a paste that is then extruded in the form of a filament, after which the paste is expelled and the particles of metal are welded together by an electric current. This complicated method of forming the filaments is due to the fact that tungsten is not sufficiently ductile to be drawn out into fine filaments. An English concern has just discovered a method of producing drawn filaments of tungsten, and the General Electric Company has also just announced the discovery of a method by which tungsten may be rendered sufficiently ductile to permit of its being drawn into fine wires. The drawn tungsten filament is stronger than the filament made by the "sintering" process.

**The Junior Wireless Club** is making a strong protest against bills that are now before Congress aiming to restrict amateur work in wireless telegraphy. Particularly objectionable to them is the proposed annual fee of $100, to be exacted from all wireless stations. As there are between 40,000 and 50,000 boys in the country with their own wireless equipments, this virtually represents a tax of between four and five million dollars. Of course, very few boys could pay a $100 fee, and the result would be that practically all amateurs would be eliminated from wireless experimentation. It does not seem as though this would be advisable, because many of the improvements in wireless telegraphy have been the work of amateurs.

**Explosions** are often caused in flour mills and breweries by nails or other iron particles that find their way in the grain, and which when they strike the steel rolls of the mills produce sparks and ignite the finely pulverized material about them. Recently a large malting concern that had been troubled by many such explosions installed a set of electro-magnets over which the grain is passed before being prepared for shipment to the breweries. All iron particles in the grain are thus picked up by the magnets and 800 to 1,000 bushels of grain are cleaned per hour. When the magnets have collected a large amount of metal, they are swung to one side, de-energized, and swept clean of any particles adhering to them by residual magnetism. Since the installation of these magnets, there have been no explosions in the mills.

**A series** of tests was recently conducted for the Board of Education of Newark to determine the best form of lighting for schoolrooms. The rooms in which the experiments were tried measured 22 by 34 feet and were 12 feet high. Three systems were tried, consisting of twenty-two 16-candle-power lamps, five 75-candle-power graphitized filament lamps, and five 100-watt tungsten lamps with glass reflectors and frosted tips. The tungsten lamps were the most economical and gave by far the best light at each desk, as was determined by illuminometer readings. A similar investigation has been made in Boston, where it was suggested that the room be lighted by lamps placed along the side walls just under the ceiling in boxes with prismatic glass bottoms, which would cast the rays into the room at the desired angle.

## SCIENCE

**According** to the Journal Soc. Chem., it has been shown that small quantities of bismuth exert little or no influence on the chemical relation of copper and nitric acid.

**At a recent** meeting of the Royal Society of Medicine in London, a warning was sounded against the reckless use of radium. Even the reputed favorable effects of radium in the treatment of cancer were sharply criticised.

**The Seine** is the fourth largest river in France, ranking in size below the Loire, the Rhone, and the Garonne. Its drainage basin (30,870 square miles) is larger than that of the Susquehanna (27,400 square miles) or of the Sacramento (27,100 square miles).

**Sir John Murray**, K.C.B., the well-known naturalist, will head an expedition for biological and physiological exploration in the North Atlantic. Although much has been done in this region, an enormous field is still unexplored. Sir John sailed from Plymouth on the 14th. The sea will be explored to the depth of 1,800 feet.

**It is said** that Prof. Karl Harries of the University of Kiel has produced a synthetic rubber. The actual details of the process are not before us. Attempts such as these have been made again and again, but with no commercial success. The most that can be said for them is that they indicate the possibility of producing a synthetic rubber from turpentine at some future time.

**Dr. Robbins**, an English writer, calls attention to the development of the jaws of English boys who were taken out of the streets of London and sent into the British navy. He says: "Undoubtedly the important notable improvement in them, next to their superior stature and healthy appearance, was the total change in the shape and expression of their faces. On analyzing this, one finds that it was to be mainly accounted for by the increased growth and improved angle of the lower jaw." The change is due to the rations of "hard tack" and "salt junk" upon which these lads had subsisted.

**Savants from all parts** of the world will gather in Pasadena, Cal., next August, and will ascend Mount Wilson. Almost one hundred leading scientists of Europe and America have accepted invitations extended by the Carnegie Solar Observatory to participate in the third regular convention of the International union for co-operation in solar research. Among these will be Prof. Ricco of Mount Etna Observatory, Sicily. Germany, England and France will send four delegates each. On Mount Wilson are mounted the largest telescopes in the world for the study of the sun, and by August a new one will have been completed. This will be a 150-foot tower telescope, which will have more than double the power of any other instrument of the kind for photographing the sun's rays.

**Some years ago** several applications of the Thorp plane replica diffraction gratings were exhibited, notably their use with an opera glass for eclipse work. The only disadvantage of these is the necessity of employing glass lenses for collimator and telescope, which not only increase the expense but render the instrument somewhat limited, in that the ultra-violet region of the spectrum is more or less absorbed. Recent experiments by Mr. C. P. Butler have shown that concave replica gratings can be made to give very satisfactory results, and by slight modifications of the design of mounting this form of spectroscope may be employed for any investigation for which the ordinary spectroscope is fitted. A valuable feature appears to be that the radius of curvature may be varied within very wide limits, thus providing instruments of different dispersion and light-grasping power.

**The orbits** of the two inner satellites of Uranus were determined by Newcomb in 1875. At that time no appreciable eccentricity could be certainly proved to exist in either orbit. Osten Bergstrand, of the observatory of Upsala, Sweden, has recently published a discussion of the observations which have been made of these satellites since 1894, chiefly with the great 36-inch equatorial of the Lick Observatory. Bergstrand finds that the orbit of the second satellite, Umbriel, is clearly elliptical and that its apse, or "periuranus," is subject to a secular displacement, from which a flattening of Uranus at the poles may be inferred, and the value of oblateness approximately calculated. No conclusive result in regard to the oblateness of the planet has been obtained by direct observation. Bergstrand deduces from the observations, also, the values of the major axis and eccentricity of the orbit of Umbriel and that of the mass of Uranus, which he finds equal approximately to 1/23300 the mass of the sun. This value in combination with Barnard's value of 2.075 seconds for the angular equatorial radius of Uranus, makes the density of the planet 0.16 that of the earth. Bergstrand's values for the mass and density of Uranus are smaller than those which have hitherto been accepted.

# THE EROSION OF BRONZE PROPELLERS

## ONE EFFECT OF THE HIGH SPEED TURBINE

The introduction of high-speed turbine engines has produced a serious amount of erosion in propellers made of high tension bronze—a material which until recently showed no serious erosion effects. The trouble which the bronze manufacturer has been chiefly occupied in preventing was corrosion both chemical and galvanic but erosion or the mechanical breaking up of the material by the action of the water, was formerly never considered. One of the most astonishing cases of severe erosion occurred in the case of the Cunard liner 'Mauretania', for after she had been in service about three months, on drydocking the ship it was found that all the bronze propellers were badly eaten away, those at the stern being least affected. The area that suffered most was situated about two feet from the root and toward the after edge of the blade. The corroded area amounted to three or four square feet, and the metal had been eaten away in depths which varied from a quarter of an inch to two and a half inches.

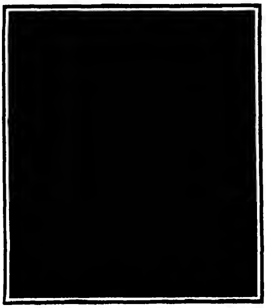
A very thorough examination of the problem was made by Dr Oswald Silberrad who, after an exhaustive series of laboratory and other experiments, determined that the deterioration was due to erosion, and found that it could be prevented by the use of a special bronze alloy whose chemical and physical properties were designed specially to meet the condition.

Dr Silberrad came to the conclusion that since the material withstood the old conditions of propeller service, the primary cause of the deterioration was due to the modified conditions of higher propeller speed, etc. In discussing the new conditions he calls attention, first, to the terrific surface friction of the water. The "Mauretania" was originally fitted with four three-bladed, built-up propellers, of the usual high tension bronze that has been employed for many years for the propellers of Atlantic liners. They were a little less than 17 feet in diameter, and upon the westward voyage the average revolutions of the engines were 174, the horse-power developed being about 68,000. The perimeter of each propeller traveled through the water in a helical path at a speed of about 105 miles per hour, and transmitted to the water during the whole of the voyage no less than 17,000 horse-power. "The consideration of these figures," says Dr Silberrad, "enables us to realize that, under such conditions, the water becomes a very rough file for any alloy to withstand, and when the standard bronze, which has proved so serviceable in the past was subjected to these conditions, we can scarcely be surprised that it failed."

A curious feature in the problem was the wide and marked divergencies in the degree and position of the deterioration in the various propellers examined. Thus in the sister ship 'Lusitania," where the conditions were at first apparently identical, the backs of the propellers were quite as much affected as the faces. Moreover, the propellers of certain destroyers showed a maximum damage at the base (see illustration) where the helical velocity is least. In looking for secondary causes, "dirt in the castings" was excluded because the eroded castings proved to be exceptionally free from dirt, "galvanic action" also was shut out by the fact that analysis showed that no large concentration of copper had occurred on the eroded surface. At the same time the areas of maximum deterioration do not coincide with the view that erosion is *alone* the primary cause, since these areas in no case occur at the extreme tips of the blades, where the helical velocity is greatest.

After a prolonged research, involving the examination of a large number of cases of propeller deterioration, it was proved that the trouble was *primarily* erosion, although the degree to which secondary causes entered into the problem varied more widely than was anticipated.

In a series of tests to determine the relative resis-



**One of the new solid propellers of the "Mauretania" of special turbine alloy, which fail to show any erosion.**

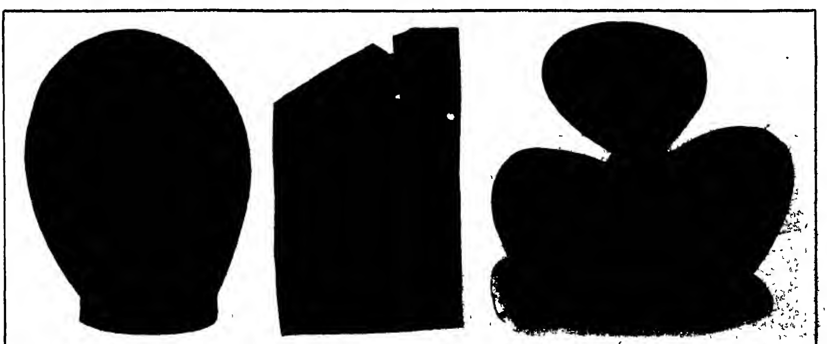
tance to erosion of a large number of different alloys it was found that the number of hours necessary to produce a certain deterioration varied from 24,700 hours, the time of the regular standard bronze, to 117,200 hours for Parsons new turbine alloy, which was used to cast the new four-bladed, solid propellers with which the "Mauretania" and "Lusitania" have been equipped. An examination of these propellers, each of which weighs about twenty tons, was made after they had been running for nearly six months, by the surveyor for Germanischer Lloyd, who reported that he found them in perfect condition. It is significant, also, that since their adoption for the forward, or wing shafts each of these ships added about three-quarters of a knot to its previous best speed. As the same four-bladed propellers are to be fitted to the other two astern shafts it is likely that the transatlantic speed may be raised this summer above the 26.06 average at which it now stands.

---

It was in 1850 that Mr. Hind read a paper before the Royal Astronomical Society in which he traced the appearances of Halley's Comet through the ages with the help of the Chinese annals, which had only recently become known in Europe. Although he was sometimes wrong, he was nearly always right. He believed that in the Chinese annals he had found credible references to Halley's Comet back to the year B. C. 11. He regarded it as certain that Halley's Comet reached its perihelion in 1378, and therefore, allowing the normal periodicity, he looked for some mention of it about the year 1301. The Chinese annals definitely describe a great comet in that year. There was one European account of it by Friar Giles which was not reconcilable with the Chinese record. If the Chinese were describing Halley's Comet it seemed that Friar Giles certainly was not. Hind was led to an examination of Giles's credibility. He discovered that his account of another comet in 1264 was so contradictory that he had no hesitation whatever in preferring the Chinese statement for 1301, and concluded that the comet of 1301 was Halley's. He believed that the preceding return of the comet was in 1223, when, in July, shortly before the death of Philip Augustus, a comet was seen for eight days in the evening twilight. The Chinese annels do not mention this comet, but they mention comets in the years 1222 and 1224, neither of which Hind thought closely resembled Halley's Comet. Cowell and Crommelin have shown that Hind was wrong about the particularly bright comet of 1222, which was unquestionably Halley's Comet. Not all of Hind's "ascriptions," as art critics say, are reconcilable with Cowell and Crommelin's latest calculations, but enough is established on all hands to prove that Halley's Comet has been appearing ever since the history of the skies has been written.

---

A new type of locomotive designed to secure smokeless combustion of bituminous coal has recently been tried on two or three of the railways entering Chicago. The apparatus is designed to operate on the coking principle. The coal is so fed as to admit of the gases being first consumed, the resulting coke being fed to the grates and consumed without the black smoke of more rapid and incomplete combustion. Within the fire-box is a magazine which may be changed in quantity, a ton at a time if desired, from which the coal is automatically fed to the fire. A rotary fan underneath the fire-box affords a supply of fresh air to assist the proper combustion of the gases before they escape through the tubes, and supplies the necessary draught. The arrangement has been used with some success in connection with stationary plants, but there appears to be some skepticism whether the fire thus produced will be of sufficient intensity for locomotive purposes.



**Erosion of bronze blade of "Mauretania" after three months' service.** **Portion of torpedo-boat destroyer showing severe surface erosion.** **Bronze propeller of a destroyer, showing pronounced erosion about the root section.**

THE EROSION OF BRONZE PROPELLERS.

# HOT-AIR SHOWER BATHS FOR VETERINARY PURPOSES

BY DR. ALFRED GRADENWITZ

Electric hot-air fans have been employed for some time in medical practice, and have undergone during the last few years most interesting alterations as regards form and use. In their original form they were used for drying hair by means of an air current produced by an electric fan, and heated by an electrical resistance.

THE HOT-AIR VENTILATOR. A SERIES-WOUND ELECTROMOTOR IS HIDDEN IN THE HANDLE.

This current of heated air was soon found to possess striking curative effects. In connection with maladies such as gout, rheumatism, neuralgia, etc., a daily application lasting ten to fifteen minutes would alleviate, and in the case of prolonged treatment even cure these ailments. It is true that the limbs affected being especially susceptible to cold after the treatment had to be carefully protected by warm clothing.

Some time after the new treatment had been introduced in medicine hot-air currents were found to exert striking curative effects on morbid tissues and in furunculosis, abscesses, etc., on account of the hyperæmia (abundance of blood) produced by them. Thus hot-air shower baths have been adopted in an extremely short time, not only in hospitals and sanitoria, but in the consultation rooms of specialists as well as those of the ordinary practitioner. Their ease of handling, the readiness of the hot-air fans for use in working at a moment's notice after being connected with an ordinary contact box, and the control of the heat effects at will by a special switch have greatly facilitated the adoption of the shower baths. In fact, hot-air ventilators are able to generate in half a minute a strong air current up to 212 degrees F., a result impossible with any other apparatus.

The electrometrical instrument factory of Dr. Richard Heilbrun in Berlin has recently extended the use of hot-air shower baths to veterinary practice. The ventilator used in this connection comprises a series wound electromotor hidden in the handle of the apparatus. The electrical radiator heating the drawn in air current to a temperature up to 212 degrees is carried by a connection tube 40 millimeters in diameter. The weight of the apparatus is about 2 pounds, the current consumption of the motor under a tension of 220 volts is 0.2 ampere and that of the radiator 2 amperes. A nickel funnel 100 millimeters in length and 20 millimeters in diameter fitted over the mouth piece allows a hot-air current of increased intensity to be generated, which is particularly valuable in connection with a localized treatment.

As dogs and horses are especially susceptible to

THE HOT-AIR SHOWER BATH AS OPERATED IN LOCALIZED TREATMENT

catching cold, the hot-air shower bath affords an effective means of alleviating and curing their ailments, even the most nervous dogs becoming [illegible] to the unusual treatment after its first application.

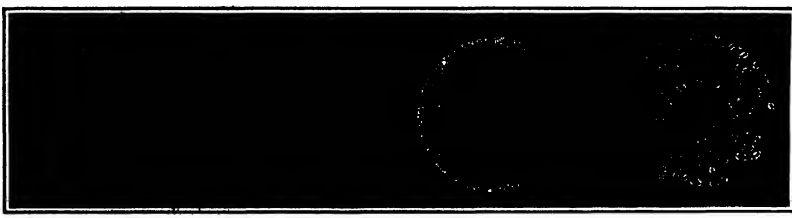
# THE MICROSCOPE AS FOOD DETECTIVE

BY P. HARVEY MIDDLETON

Probably no other form of wrongdoing so vitally affects us as tampering with our foods and medicines. Of course the law allows the presence of a certain percentage of preservatives in foods, but it is the excess of this allowance that causes a continuous war to be waged between the traders and the representatives of the law. And so profitable a proceeding is the importation of inferior material into the food of the American public that many large firms employ skilled chemists at a high salary in order that their expert knowledge may assist them to drive a coach and four through that most far-reaching and radical law of modern times, the Food and Drugs Act of June 30th, 1906, and fatten on the proceeds.

In what a remarkable manner our food is tampered with may be gleaned from the fact that a large and highly trained staff of inspectors and their assistants are engaged under the Food and Drugs Act to detect offenses of this kind, and great are the difficulties with which they have to contend. For instance, it is a chemical task to prove that poisonous copper salts are applied to bottled vegetables to give them color, and a microscopic achievement to show that a concoction labeled and sold as arrowroot is no thing of the kind, but chiefly potato starch. It is difficult to prove who puts brick dust, peroxide of iron or arrowroot in a harmless looking packet of cocoa, or which hand introduces substances derived from coal tar into wines, syrups and drugs to make them more attractive to the [illegible]. One such [illegible] is [illegible] violet coloring matter [illegible] boasts a name [illegible] fifty-five letters [illegible] dlethyldibenzyldiethyltriamidotriphenylcarbinol [illegible] disulfone.

The alleged olive oil used in salads is often cotton

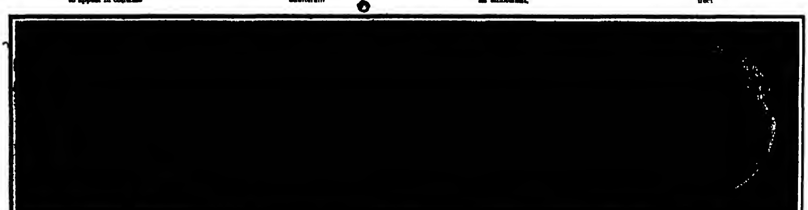


Black pepper adulterated with ground olive pits. The pepper starch has been stained black with iodin, causing the olive cells to appear in contrast.

The angular bodies are pepper starch and the rounded bodies are bean starch which is used as an adulterant.

The round grains are potato starch and the angular grains are corn starch used as an adulterant.

Bean starch photographed with polarized light showing characteristic [illegible] effect.



Chicory, showing some of the characteristic cup vessels by which it is detected when present in coffee.

Cream thickener composed of corn starch (angular bodies) and gum tragacanth (laminated portions).

Pollen from honey. The various forms indicate the different plants visited by the bees.

Celery seed adulterated with ground rock, the latter indentified by its angular form.

THE MICROSCOPE AS FOOD DETECTIVE.

seed oil, and such substances as burnt sugar Cayenne pepper, acetic ether, tannin, crude cream of tartar, and French plum juice are frequently imported into brandy and whisky

The term 'adulteration' when applied to food or drugs is broad in its scope, but has been given a well defined legal meaning In general it may be said that adulteration consists in injuriously subtracting from a substance any part of its natural or inherent qualities or adding to it any ingredient which would render the article of a different nature than that of its expressed and natural form

Almost coexistent with the growth of this wonderful country, and seemingly as a part of the fierce business competition which has insidiously developed, this evil of food and drug adulteration has arisen The conditions of substitution and adulteration of foods and drugs were little short of deplorable less than a decade ago For seventeen long years the bill which has now become the Pure Food Law lay at the door of Congress and during all that time it was bitterly opposed by the manufacturers who had so long enjoyed unmolested their privilege of supplying the dinner tables of the nation with impure foods misleadingly labeled

While this act has done much good, there is still a very considerable amount of adulteration practised Pepper adulteration is still remarkably common and "Pure White Clover Honey is concocted by the imitators of the busy bee from glucose Other enterprising manufacturers will cause two grains of Cayenne pepper to grow where only one grew before by making one of the grains grow out of sawdust Ground peas and beans may be found in black pepper, and celery seed may be adulterated with forty per cent of powdered rock

In order to run down one class of food faking, the pure-food experts at Washington have introduced the microscope into their work It can be readily understood how gross adulteration may be detected by a simple microscope, as for instance when foreign seeds gravel, or powdered rock have been mixed with whole small spices. The adulterant may be of such a character as to escape the notice of the ordinary buyer, though with even a small lens or reading glass the foreign substance may be seen to be very different from the true spice

The usefulness of the simple magnifier in examining food and drug materials, however is of little value for the examination of products which are made up of small particles such as flour, ground spices and powdered drugs In such cases recourse must be had to the compound microscope with a magnifying power ranging from fifty to four hundred diameters

The world's supply of starch comes for the most part from a limited number of plants, twelve or fifteen include nearly all that are of much commercial importance To the naked eye these starches all appear as a fine white powder, but under a microscope grains or granules are seen which vary more or less in shape, size rings nucleus and action toward polarized light. Some of the grains are almost spherical, others are angular or ovoid and still others are very irregular in outline In diameter they vary from one-tenth to one-thousandth of a millimeter In no variety are all the starch grains of one size, but usually there are fairly well-defined limits The way in which they sometimes vary will be seen by reference to the photographs reproduced in this article Most of the grains show, more or less clearly fine lines of rings upon the surface. In some varieties these are arranged concentrically, while in others they are eccentric

"A hilum (nucleus) whose form and position varies widely in certain species commonly occurs in starches," says B J Howard, who has charge of this microscopical work in the Bureau of Chemistry at Washington "In some it is at the center as in corn and wheat starches, in others near one end, as in potato and arrowroot When viewed in polarized light starches show more or less strongly a cross with the bars passing through the hilum Wheat starch has a central cross while in maranta it is eccentric and well defined Bean starch which illustrates the leguminous type, has a spindle-shaped cross In the oat a number of starch granules are joined together forming a mass When these masses of starch are examined under polarized light individual grains in the mass have their own individual effect, and interfere so with each other that there results little more than a hazy glow of light"

By becoming familiar with these characteristics it is possible to identify with considerable accuracy nearly all of the commercial starches Potato starch adulterated with corn starch wheat with corn flour, and buckwheat with wheat are examples of those most easily detected One of our photographs shows a picture of potato starch adulterated with a considerable amount of corn starch The grains of the latter are easily distinguished by their angular form

Another interesting application of the microscopic method of food analysis is found in the examination of spices. Many of these naturally vary so widely as to ash, fiber, etc., and in taste that it is impossible to identify certain kinds of adulteration by chemical and physical means alone. A study of the structure of pure samples will usually fit the analyst to detect adulteration in the ground spices as well as to identify the adulterant used In order to work most intelligently, however it is imperative that the analyst should have a good foundation in histological botany, since in this class of products the plant cell in its various modifications becomes the means of identification. In an examination of this sort nearly all kinds of plant tissue are to be considered, because some spices are derived from roots, as ginger, some from barks, as cassia and cinnamon, some from flowers, as cloves, some from seeds, as mustard, some from fruits, as red pepper, black pepper, etc, and some, such as sage and thyme, from leaves.

"Unfortunately," says Mr Howard, "most of the substitutions used for adulteration have a structure very different from the genuine spices For example, although pepper may be adulterated with ground peas, or beans, it may not always be detected by chemical means, especially when olive pits or pepper shells have been added to counteract excessive starch present in beans A microscopical examination will reveal such adulteration at once by showing the presence of the large starch grains characteristic of certain legumes. In pepper the starch is present in angular masses made up of small grains."

It sometimes occurs that a manufacturer has added so large an amount of corn meal or foreign ground shells and fruit stones to a pepper as to make the adulteration apparent to the taste by the lack of pungency, which is often corrected by adding a small amount of Cayenne pepper A sophistication of this kind can be readily detected by the microscopic method of analysis, because the tissues added are so distinctly different from normal pepper tissue In one of our photographs is shown the microscopic appearance of a sample of pepper which was grossly adulterated with ground olive stones The starchy material has been stained black in the picture, while the partly clear portions, more or less oblong in form, are the stone cells of the olive pits

The capsicum fruits are readily identified by means of certain cells found on the inner portion of the pericarp (pod) and others on the seed coats. These cells have characteristic sinuous outlines which make them easy to detect even when present in very small numbers.

In coffee and chocolate preparations roasted chicory, cereals, and peas in the case of the former and starchy materials and cocoa shells in the case of the latter, are sometimes used for adulteration Coffee, being the seed of a plant has a structure which is very different from chicory, which is a root. The cell walls of coffee have a characteristic beaded appearance which is present in but few other seeds Even after roasting and grinding these beads can be easily distinguished while chicory contains sap vessels by which it can be detected

Chocolate and cocoa are made from the seeds of the cocoa plant, to which foreign starches are sometimes added Cocoa beans contain naturally a considerable amount of starch The grains are small in size and are easily distinguished from the starchy adulterants, such as corn and wheat flours or potato corn, and arrowroot starches An artificial chocolate coating has been examined which was composed of cocoa shells, corn starch, beef tallow and some mineral matter, probably used as a coloring substance

In the production of artificial jellies jams, and some kinds of confections various thickeners are used among which might be mentioned gelatin, starch, agar-agar gum tragacanth, and gum arabic Some of these are difficult of identification, while others can readily be detected Agar-agar is a product made from certain seaweeds, and usually contains the siliceous shells of diatoms These shells are characteristic and quite easily detected in the sediment from the bottom of a dish after the material has been digested with dilute nitric acid One of our photographs shows such a diatomaceous shell obtained from a sample of artificial 'lemon slices" in which was found that the jellying material was agar-agar

Starch can easily be detected by microchemical and microscopical tests. Gum tragacanth and some other gums of this class contain a certain amount of small starch grains. When allowed to swell in water, a delicate laminated structure is developed by which these gums are disclosed even in such products as ice cream and marmalades.

A sample of thickener for cream composed of corn starch and powdered gum tragacanth is shown herein, and illustrates this feature quite satisfactorily In this case the corn starch is shown plainly as the angular particles, while the striated bodies near the center of the field are swollen fragments of the gum. The microscope is also of service in the examination of certain edible fats. Thus, if pure lard is dissolved in ether and the latter is allowed to evaporate slowly under proper conditions, crystals of the lard will be formed. These, if normal, will appear under the microscope as narrow plates with chisel-shaped ends. Beef fat treated in a similar manner will normally crystallize out in sheaf-like tufts of crystals, the ends of which are nearly or quite needle-like

Another application of microscopic analysis is in the identification of the flowers from which honey is made. This is of practical value in the analysis of honeys purporting to be from certain flowers. Although bees will almost invariably gather honey from several kinds of flowers, sometimes one or another of these predominate to such an extent as to impart a distinctive color and taste, enough to allow the honey to be called by that name By microscopic examination it is readily ascertained whether a so-called apple-blossom honey or an orange-blossom honey is really largely derived from the source claimed A photograph showing several kinds of pollen found in an ordinary sample of honey is reproduced

## Correspondence.

### THE INVENTION OF THE PLAYER-PIANO.

To the Editor of the SCIENTIFIC AMERICAN

I must file a demurrer to an impression created by the illustrated article which appeared in your issue of the 9th inst., under the heading "Ringing Chimes by Perforated Music Sheets." In referring to John McTammany as one of the inventors of the player-piano, I think an erroneous impression is thus conveyed regarding McTammany's true relation to the development of the player

As a matter of fact, he is known and conceded to be the father of the player by everyone in the piano trade familiar with the player history, and his claims to its inventorship stand unchallenged up to this moment. We do not refer to McCormick as one of the inventors of the reaper or to Howe as one of the inventors of the sewing machine nor to Cristofori as one of the inventors of the piano, although other men besides those mentioned contributed greatly to the development and improvement of the aforesaid inventions.

The history of every great invention has demonstrated that some one man has stood out pre-eminently from all his fellows in the course of its development, and the player has been no exception, and the one man who above all others stands forth pre-eminent in the player field is John McTammany, while around and about him, like so many satellites, have stood other men who have contributed of their genius to develop and improve the invention In the case of the reaper it was McCormick who overshadowed all his contemporaries, on the other hand Howe was the presiding genius who led the sewing-machine pioneers, while Cristofori was the pre-eminent genius who first conceived and developed the piano

It is true that others have improved upon the handwork of McCormick and Howe as well as upon that of Cristofori, but nobody has been able to eliminate the elements which they introduced into their respective inventions, and so long as those essential elements remain in their respective devices, just so long those inventions shall be attributed to the men we have mentioned But the piano invented by Cristofori was a mute and silent piano, and such it remained from the time it was invented, in 1709, until 1876, when John McTammany breathed within its wooden walls the breath of life, and henceforth it became a living, breathing, yea, almost a human thing, until to-day it stands forth the unsurpassed and unchallenged king of musical instruments. The following definition of the player has been accepted by the piano trade as authoritative

> Player, a musical instrument consisting of a casing two actions and a series of sounding devices within the casing, one of said actions adapted to be operated manually, the other designed to be operated mechanically by means of a perforated sheet on rolls, a wind, spring, or other motor for feeding the sheet and winding the rolls, a bellows and mechanism put in motion by it for actuating the sounding devices of the automatic action foot pedals or power for driving the motor, and means for controlling the tempo and varying the expression."

Now the first man to embody the foregoing elements in a musical instrument was John McTammany, and it follows that if McCormick is the inventor of the reaper, Howe of the sewing machine, and Cristofori of the piano, by reason of the fact that they were the first to embody in their respective devices the essential elements which distinguished those inventions to-day, and the elimination of which would make them worthless, then by the same token John McTammany must be regarded as the father of the piano-player mechanism, for no practicable or salable player has yet been made that did not contain the elements first embodied by him in a practical working instrument as early as 1876, and which was publicly exhibited in St. Louis the same year and described by the press of the country at the time, while your own files will show that Munn & Co applied for a patent on this identical invention on behalf of McTammany on September 7th of the same year, and prior to that nothing in the nature of the present player was known to the Patent Office or the public, either of this country or Europe.

Editor Music Industry.

# THE SOLAR AND LUNAR ECLIPSES IN MAY, 1910

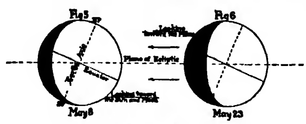
BY FREDERIC R. HONEY, TRINITY COLLEGE

An examination of some of the conditions which govern the moon's motion reveals the great complexity of the lunar problem While the earth's volume is nearly fifty times the moon's volume, its weight is more than eighty times—the density of the moon being only six-tenths that of the earth. As a consequence, the common center of gravity of the two bodies is within the earth at a distance of over a thousand miles from its surface, and it is this point which moves in an elliptic orbit around the sun. Twice each month the earth and the moon exchange places with reference to the sun The moon's orbit is an ellipse with the earth at one focus, and the plane of the orbit is inclined at an angle of a little over five degrees to the ecliptic. The eccentricity is one-eighteenth, but the elliptic form is subject to great variations The moon revolves around the earth at an average velocity of a little over five-eighths of a mile a second, but its path in space is the resultant of its motion in its orbit and of the earth's motion at a velocity of eighteen and five-tenths miles a second, illustrated at Fig 1 The arrows $A$ and $a$ represent the velocities of the earth and the moon in their respective orbits. When the moon is at $M$, between the earth and the sun, the direction of the moon's motion is opposite that of the earth At $M'$ the earth and the moon are moving in the same direction At these points and at any intermediate point $M''$ or $M'''$ the moon's path is the resultant of the two motions. The plane of the moon's orbit rotates slowly in a direction contrary to her orbital motion, and the perigee has a slow motion in the same direction as that of the moon

While the conditions which determine the moon's path are complex, observations extending over long periods of time show regularity in the recurrence of eclipses. (See SCIENTIFIC AMERICAN, September 12th, 1908) The direction of the line of nodes is shown in the plot of the earth's orbit for November 1909 at the date of the last lunar eclipse, and also in the plot for May, 1910 During the interval this line rotates through an angle of over nine degrees If the positions of the earth at the dates of the solar and lunar eclipses in May be carefully plotted, and the moon's orbit magnified, the situation of the moon relative to the ecliptic may be determined by an inspection of the plot The arrow $A$ shows the direction of rotation of the orbit, and $a$ that of the moon's motion

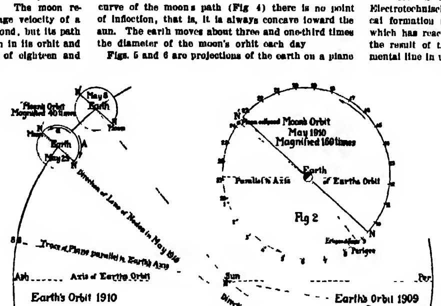
At the date of the solar eclipse (May 8.7 d) the moon's orbit radius is projected on the plane of the ecliptic in the earth's orbit radius, and the moon's position is in that part of the orbit which is below the ecliptic. This is shown more clearly in Fig 2, in which the orbit is magnified one hundred and sixty times. The moon's position is shown at Greenwich noon from May 1st to the 28th, and also at the dates of the eclipses On May 8.7 d, the date of the total eclipse of the sun, the moon will be nearer perigee, and approaching the ascending node $N$ which will be reached between the 9th and the 10th The enlarged plot shows clearly that the moon will be below the ecliptic Its shadow will therefore be projected on the southern hemisphere The path of totality will be between latitudes 40 and 70 degrees south, and as a partial eclipse it will be visible in Australia, New Guinea, and Java. On May 23.74 d the moon will be below the ecliptic, and will pass the descending node $N'$ on the same day The beginning of the eclipse will be visible in portions of Africa, southwest Europe, North America except Alaska, South America, and the southern Pacific Ocean, the ending visible in South America, North America excepting Alaska, and the central and southern Pacific Ocean.

In Figs. 3 and 4 a portion of the earth's orbit in May and the moon's orbit are drawn to the same scale, showing the projection on the plane of the ecliptic of the moon's path in space between the dates of the eclipses. The plot by the larger scale (Fig 3) shows how points on the curve are obtained between the dates May 8th and 11th, Greenwich noon. The moon's orbit radius is drawn parallel to the position for each date in Fig 2, and the curve is traced through the positions of the moon The orbit of the moon at the date of the solar eclipse is also shown In the curve of the moon's path (Fig 4) there is no point of inflection, that is, it is always concave toward the sun. The earth moves about three and one-third times the diameter of the moon's orbit each day

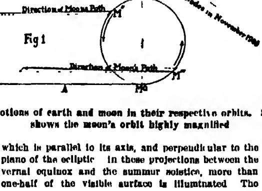


The earth during the May eclipses.

Figs. 5 and 6 are projections of the earth on a plane which is parallel to its axis, and perpendicular to the plane of the ecliptic In these projections between the vernal equinox and the summer solstice, more than one-half of the visible surface is illuminated The arrows show the directions in which the eclipses will be observed.



Velocities and motions of earth and moon in their respective orbits. Smaller diagram shows the moon's orbit highly magnified



Projection of the moon's path on the plane of the ecliptic.

### The Fast Mail of the Future.

The principle of a mechanical delivery of mail has been established by the highly successful use of the pneumatic tube. This device is not the least conspicuous among the technical installations in the large cities, and probably will be applied to a greatly ramified postal enterprise in the near future The chief question that arises in consequence is whether a system of delivery similar to that of the pneumatic tube can be installed for greater distances and at the same time afford an enlarged rate of speed At the present day pneumatic postal delivery is found only in the large cities, and being restricted to local business, asks a rather exorbitant price for such service It is plain that the employment of such a mode of distribution to distant points consequently among the cities also must give a wholly new aspect to the present systems of commercial intercourse The first attempts made for the development of this idea were those of a company formed in Paris. A recent number of Der Electrotechnische Anzeiger states minutely the technical formation and other progress of this enterprise which has reached the stage of thorough practicality, the result of the quite facile function of the experimental line in use For the near future the Paris company intends to connect the larger cities of France through electric postal routes that shall not have frequent intermediate stations The rate of speed proposed is 250 km (155 miles) an hour The capacity of the automatic express car is to be 2 cu m (2.6 cu yds) approximately and the weight of a load consisting of letters and other postal pieces of smaller dimensions shall not exceed 100 pounds

The roadbed so to speak, on which such delivery shall be practised must of course, be separated definitely from all other avenues of physical communication must be inaccessible to the public and this result can be procured only either through an elevated road or through a tunnel For their experimental road the company has chosen the latter device and has built a tunnel which contains two rails, one above the other and of which the cross-section measures 8 sq m (9.5 sq yds.) For the round trip beginning at intermediate stations branches and switches are provided The function of the experimental road, procured through an electric circuit, is such that the highest speed is reached very quickly The cars have two wheels which run on the lower rail and also two rollers which follow the upper rail and hold the cars in position The cars, moreover have a middle compartment for mail, and other divisions for the motors and the devices used as brakes In front and behind the body of the cars is a conical point to diminish the resistance of the air The frame of the cars is of iron exclusively The motors are attached to the frame by means of levers which swing around an axis perpendicular to the direction of travel The current is applied through an upper conduit and the brakes are worked by compressed air as well as by the resistance of the air artificially increased by the wings attached to the sides of the front end of the cars These wings stretch out to catch the air This device can stop a car within one minute and in a distance of three kilometers after the current is interrupted but is used only as an accessory to prevent the too rapid destruction of wheels and rails through the exclusive use of the rail brake, a source of most active friction

---

A patent recently granted to Carl Farkas of New York, describes a method for making incandescent lamp metallic filaments which consists in producing on a conducting core a highly refractory coating by decomposing in a vacuum the vapors of a salt of a highly refractory metal in the presence of vapors of pyrogall, with final reduction in a vapor of hydrogen In detail, the vapors of chloride of chromium and pyrogall are introduced in a vacuum containing the conductor, which serves as a core which latter is then heated by the passage of a current the vapors are thereby decomposed, nascent carbon from the pyrogall acting as a cement chromium probably being formed When the coating has thus been produced the vapors are removed and hydrogen gas introduced, whereby the deposition is reduced to metal

Some of the little craft that competed in the racing.

# MODEL MOTOR-BOAT RACING

BY H. D. JONES

Model motor-boat racing, a new sport, has caught the popular fancy in England, and is being taken up in all the large cities. With a view to encouraging owners of models to enter their boats in the various competitions, challenge cups are offered by the clubs, and the conditions are made so broad that every designer feels that there is a chance to win a trophy. The prizes are awarded for speed, for workmanship, for the general appearance of the models, for the behavior of the machinery and the performance of the boats while on the water.

Not less than 5,000 spectators gathered recently at Clapham Common, one of the many open spaces in South London, to witness the regatta on the lake. The competition brought to the front some of the speediest racing models, some particularly fine ones of saloon steamers, liners, and torpedo boats, and other craft that were built for appearance rather than for racing.

The rules of racing were very simple. Each owner started his model boat to run a straight line over the course at the end of which officials appointed for the purpose waited to "catch" the racers and return them to their owners. After the models were once started no interference was permitted, the ability of the unguided boat to keep in a line for the finish of the course being part of the qualifications for prize winning.

Over a course measuring fifty-one yards, four boats were started in the first race, at which the accompanying pictures were taken. The best time was made by a steam hydroplane, the "Folly," in 9 1-5 seconds, "Sunny Jim," a gasoline craft, did the distance in 12 3-5 seconds, "Leda IV," a steamer, covered it in 15 4-5 seconds, and the fourth steamer, "Idunno," in 21 seconds.

On running off the final heat, boat against boat in pairs, the "Sunny Jim" scored three wins, the "Leda IV" two wins and the "Idunno" one win thus taking first, second and third prizes in the order named. The prizes were silver cups. The "Folly," the fastest boat in the eliminating trials, unfortunately ran off her course in the finals through her propeller fouling, and not being able to get going in the others, she had to give her opponents a walk-over.

Steering troubles were responsible for many awkward results in the other races. While hailed by the spectators as adding greatly to the enjoyment of the regatta, the failure of the little craft to keep their pointing and the perversity of the machinery when left to its own resources proved sources of great disappointment to the owners of models that failed to keep a true headway. Boats that had run as true as a die on practice spins exhibited a tendency at the regatta to run anything but straight, or not to run at all. Gasoline motors refused to start, pumps gave out, boilers leaked and the models exhibited a crankiness that showed there is a lot of improvement necessary before this sport can be brought to perfection. But that is why the regattas are encouraged. The weak points of the models are strengthened, and motor-boat building is benefited as the result of the lessons learned from the eccentric performances of the models in the cup races.

The reliability of electric power in model regattas was demonstrated again and again, one finely-modeled liner, the "Fairholme," although not built for speed, scoring through the certainty of her performance and the untrustworthiness of some of her competitors. The surprise of the meeting was the performance of a finely modeled gasoline boat, the "Silver Dart." So fast was this entry, that the officials stationed to catch the models at the posts could not reach her when a little off the line, and she swerved away. Heading off down the pond, the little boat eluded a second attempt at seizure, and before she finally came to hand she had completed two round trips in brilliant if somewhat erratic fashion, to the admiration of the spectators.

The expediency of running the regattas on a circular instead of a straight course is also engaging the attention of the experts, the difficulty of handling and controlling the big fast boats being very evident. In sending these speedy craft on a straight run across a small pond serious accidents seem unavoidable. One beautiful model, the "Moraima II," after accomplishing several fine sprints, eluded the catchers, dashed off on a course of her own, and wound up a series of mischievous gyrations by running full tilt into the bank, seriously damaging her hull and deranging the machinery. On a large lake, with a round course, such accidents, it is thought, might be avoided by a circle of catchers standing ready to keep the boats on their way until the distance is completed.

The model motor-boat regattas have justified their existence by promoting improvement and bringing unknown designers and inventors of motor-boats and motor-boat machinery to the front. Instead of proving their boats in timid retirement on some out-of-the-way pond, a test that affords no possibility of comparison with the work of other designers, a number of men with kindred ambitions are brought together in these challenge meetings, and the test of the new boat's capabilities is thorough and convincing.

The sport has progressed so far that a national challenge cup is ready for the competing designers and model owners of the United Kingdom, and the various clubs are about to hold a general meeting to draw up rules for the government of the cup regattas. Naval men are especially interested in the exhibitions. At the regatta, which was the subject of the accompanying pictures, Lieutenant William Barrett, R.N., attended with a party of naval cadets and rendered many services to the committee.

### Cost of 20,000 Candle-Power Street Lighting Plant.

BY ALTON D ADAMS

As tungsten lamps require only 36 per cent as much energy as the carbon type for equal illumination, they have greatly reduced the cost per candle-power of incandescent street lighting.

What can be done with such lighting in a small town is illustrated by the following costs and operating expenses for a plant to generate and distribute tungsten street lamps of 20,000 candle-power total.

Unlike the merely nominal rating of arc lamps, which are a number of times their true candle-power, the tungsten lamps are rated at their actual mean candle-power in horizontal directions.

The capacity of 20,000 candle-power is selected as nearly suited for street lighting in many medium and small towns, according to the density of illumination required. If lamps of 40 candle-power are selected the capacity named amounts to 500, and with lamps of 80 candle-power the 20,000 candle-power capacity will operate 250, the efficiency being the same in either case.

With 500 of the 40-candle lamps spaced 100 feet apart, or 250 of the 80-candle lamps 200 feet apart, 50,000 feet in length of streets may be lighted much better than is usual in small places, while ordinary results may be obtained by spacing the 40-candle lamps 200 feet apart or the 80-candle 400 feet apart from 100,000 feet, or 19 miles, of streets.

In the following estimates of the first cost and operating expenses of a 20,000 candle-power plant, it is assumed that each part of the equipment, from the generators to the poles, is used merely for the purpose of street lighting, so that both the fixed and operating expenses for this lighting are greater than they would

ful in connection with commercial service under like conditions.

The estimate of first cost covers a suitable plot of land, a station building of brick, concrete and steel, a storage tank to receive petroleum by the carload, a crude-oil engine and accessories, an electric generator with all necessary apparatus and instruments, pole lines on 56 000 feet of streets, circuits on these poles for the distribution of tungsten lamps of 20,000 aggregate candle power in any desired sizes and fixtures on the poles for 500 of these lamps all erected and connected complete and ready to operate

For this 20 000 candle-power plant as above with 500 lamp fixtures erected the total first cost is $14 200 or 71 cents per candle-power capacity giving $28 40 per 40 candle lamp This cost of plant is based on present market prices of materials labor and apparatus and assumes ordinary conditions at the place of erection In places where prices and freight rates are higher than is usual in the eastern half of the United States an increase of cost would result

Operating expenses of the above plant will vary with the number of lamps used even though the total candle power remains at 20 000 because of the cost of lamp renewals and also with the hours that the lamps burn yearly

All night and every night lighting to the extent of 4 000 hours per year is the most desirable and costs less per hour than lighting on moon and other schedules that run down as low as 1 500 hours yearly Such all night and every night lighting is gradually displacing the short hour service and the following estimate of operating expenses is for lamps burning 4 000 hours per annum With 500 street lamps of 40 candles each making up the total 20 000 candle power capacity of the above plant and burning 4 000 hours the annual expense of operation would be $6 200 including $710 for interest on the first cost of $14 200 at 5 per cent This expense of $6 200 covers all depreciation of the plant as well as the operating expenses that involve an immediate outlay of cash Apart from the interest charge the annual expense of operating the 500 lamps of 40 candle-power each during 4 000 hours yearly is thus $5 490 The total expense of $6 200, including interest amounts to $12 40 yearly for each of the 40-candle lamps burned 4 000 hours, or to 0 31 cent per lamp hour of burning As each 40-candle tungsten lamp operates with 50 watts, the expense of 0 31 cent per lamp hour, including interest, amounts to 6 2 cents per kilowatt hour consumed in the lamp

The same conclusion is reached by considering that at the efficiency of 1 25 watts per candle-power the production of 20,000 candle-power requires the delivery of 25,000 watts at the lamps and this during 4 000 hours amounts to 100 000 kilowatt hours, which into the annual expense of $6 200 gives 6 2 cents as before

### The Coalinga Oil District, California.

A report on the geology and oil resources of the Coalinga oil district in the western part of Fresno and Kings counties California by Ralph Arnold and Robert Anderson has just been published by the United States Geological Survey as Bulletin 398

The district described which is about 15 miles wide and 50 miles long stretches along the northeast base of the Diablo Range and includes a band of productive oil land 3 miles wide and 13 miles long at its north end and a narrow strip of oil land along its southwestern boundary

The region includes about 550 producing wells which range in depth from 600 to 4 000 feet and penetrate from 20 to 200 feet of oil sand The product ranges from a black oil of 15 deg Baumé to a green oil of 3? deg Baumé The yield of single wells differs greatly ranging from 2 to 2 000 barrels a day

The district is the leading producer in California and one of the most productive in the world Its production in 1907 was 8 871 723 barrels in 1908 it was 10 386 168 barrels, and in 1909 it was probably 17 200 000 barrels or more

The total quantity of oil thus far taken from the ground in the district to the end of 1909 was about 63 000 000 barrels of 42 gallons each leaving available a vast store of oil which has been roughly estimated as 2 747 000 000 barrels Even if this great quantity of oil is in the ground it is not possible to state whether all of it can ever be obtained

Pipe lines connect the district with the seaboard at Monterey 110 miles away with San Francisco Bay 200 miles away and with other points

The report describes the topography geology paleontology and oil in the Coalinga district which have been in part described in an earlier report published by the Survey but not now obtainable The present report includes a more complete discussion of the district and many new maps sections and other illustrations besides a paper by Irving C Allen on the chemical and physical properties of the oils Many interesting points in connection with the history of the region in past geologic ages are brought out and by means of careful descriptions of the formations a foundation is laid both for an accurate study of the occurrence of oil within this region and for the tracing of formations and oil horizons in other parts of California

The report covers 354 pages and includes 52 plates and 2 text figures The characteristic fossils of the rocks of the region are fully illustrated These afford a means of identifying particular strata from place to place and of determining the depth and position of the oil bearing sands The discussions of the oil zones of the factors affecting the accumulation and the gravity of the oil of the relations of oil and water and of the origin of the oil are of broad general interest The maps and diagrams and the detailed accounts of the geology of the wells and the character of their various products are of decidedly practical immediate value

Bulletin 398 may be obtained without cost by applying to the Director of the Survey at Washington

### The Current Supplement.

The opening article of the current SUPPLEMENT No 1790 deals with electro chemical action and boiler corrosion There is often much loose thinking and loose talking concerning the stability of ocean going steamers among those who ought to be better informed than comments made sometimes seem to indicate The matter is set right in an excellent article entitled Stability of Ships Edward Person gives some interesting cam constructions Tunnels in Being and Tunnels to Come is the title of an article which gives much useful information Richard Thirak contributes an instructive account of the German army and shows how wonderful the military system of Germany is John L Cowan contributes a good article on The Story of Silk accompanied by many excellent photographs

The newspapers recently published articles on the discovery of what was pronounced to be the greatest radium vein ever discovered in the United States in Leonia Lincoln County Montana Inquiry of the Geological Survey reveals the fact that there is very little if any truth in the statements made

View of the lake, showing the start of a race.

The "Minnehaha" being taken out for her trial

The "Sunny Jim" makes a great pace.

"Moraima," model of a steam ocean liner.

"Fairholme," an electric liner model.

"Belvedere II," a gasoline model.

"Lusus," a gasoline craft. Note the heavy wake.

MODEL MOTOR-BOAT RACING.

# ROUGIER'S SPECTACULAR MONACO FLIGHTS

BY THE PARIS CORRESPONDENT OF THE SCIENTIFIC AMERICAN

A year ago, despite the offering of substantial prizes for flights across the Bay of Monaco, no aviator made the attempt. This year, however, such big strides have been made in the art of flight that there are probably a score of aviators who are willing to try a flight over water, even without any special arrangements being made for landing in this element in case they are forced to do this.

With the spectacular flights of Paulhan and Charles K. Hamilton over the Pacific Ocean last January as an example, Rougier, a famous French cyclist and automobilist who has lately joined the flying ranks, early last month made some thrilling flights above Monaco Bay, photographs of which we reproduce.

The first flight of an aeroplane over Monaco Bay was made on March 3rd. Starting from the quay, Rougier described a figure eight above the bay and flew over Cape Martin at a height of 250 feet. He landed safely at his starting point after a flight of 4¼ minutes.

Rougier's second flight above the bay was made on the 6th ultimo in the presence of the Prince of Monaco and a large number of spectators. This and the flight the next day were each from 5 to 10 minutes' duration. On the 7th he passed 100 feet above the line of fortifications as shown in our front-page illustration, and flew straight across the bay, attaining a height of 1,300 feet above Cape Martin. Despite some rather strong wind gusts the biplane flew with steadiness and without tipping dangerously. On his way back to the starting point Rougier performed evolutions above the casino of Monte Carlo at a height of 300 feet. Finally he flew back to the rock of Monaco and landed with precision upon the narrow quay.

On March 8th he again started from the quay of the port, and flew straight for Cape Martin, across the bay. He rose to a height of 600 feet, described a circle above the bay, passed over the rocky shore at Monaco and landed at his exact starting point after a 10-minute flight. The next day he made his longest and most spectacular flight. Starting at 5:10 P. M., he rose rapidly, and described a circle above the sea. Returning he made two more circles above the Casino. Then, still rising, he flew above Mont Egel (elevation 2625 feet). Passing over the summit, he flew to La Turbie, where he turned at a height of 300 feet, and flew back to his starting point. The length of this flight was 28 minutes and 34 seconds. On March 10th Rougier again flew around the Bay of Monaco and on the 17th he made another fine flight of a quarter of an hour, in the course of which he passed 600 feet above Cape Martin, following the rocky shore of the coast in returning. These flights of Rougier on his Voisin biplane demonstrate that a considerable degree of automatic stability can be attained by vertical partitions between the main planes, and quite discredit the cabled report just received from France to the effect that the Voisin brothers have given up as impractical their system of inherent automatic stability, and have adopted wing warping instead.

Rougier flying over the yachts in the Bay of Monaco in his Voisin biplane.

THE AVIATOR FLEW OVER MONT EGEL (ELEVATION 2625 FEET), AND THRILLED MONACO FOR TWO WEEKS.

## Aeronautic News at Home and Abroad.

### LE BLON'S FATAL ACCIDENT.

Besides the record flights by Rougier above Monaco Bay, Le Blon, another famous automobile racing driver who has been flying a Blériot monoplane, made a wonderful flight above the Bay of San Sebastian, Spain, on the 2nd instant. He started in a high wind, and made several circles above the bay at a height of 150 feet, when suddenly the monoplane turned upside down, and fell into the shallow water. The intrepid aviator was instantly killed. His machine, like that of the ill-fated Delagrange, was fitted with a Gnome revolving cylinder motor of 50 horse-power. The excessive power and the gyroscopic action of the motor undoubtedly had something to do with both of these fatal accidents. Le Blon made a speed record of 46.19 miles an hour (5 kilometers in 4 minutes 2 seconds) at the Heliopolis aviation meeting near Cairo last January.

### ACCIDENT TO A CURTISS BIPLANE.

While flying in a Curtiss biplane above San Francisco Bay at Alameda, Cal., on the 5th instant, Frank Johnson plunged into the water from a height of 80 feet, owing to his losing control of the machine. Fortunately he was uninjured, and was able to extricate himself from the aeroplane (which was not badly damaged) and to swim toward the shore. He was rescued by men in a skiff.

### FIRST TEST OF PARSEVAL MONOPLANE.

The first test of Major von Parseval's large monoplane occurred on the 14th instant above Lake Plau, in Germany. This machine has a spread and length of 45 feet, and is fitted with a 120-horse-power 4-cylinder motor. The trial flights were made in a violent and gusty wind with two men in the machine. The monoplane capsized, and fell into the lake. The two engineers, Hoff and Blochman, were rescued. This machine is provided with both wheels and floats, but whether or not it started from the water is not known as yet.

### FLIGHT OF THE FABRE HYDRO-AEROPLANE.

Credit for producing the first aeroplane to rise from water and fly must apparently be given to M. Henri Fabre, who, according to the French journal L'Aero, succeeded in getting his combined hydroplane and aeroplane to leave the water and make several flights 1,200 to 1,500 feet in length at heights of from 6 to 10 feet. The experiments were made at the Port de la Mède at Martigues, a city near Marseilles. The first successful flight from water was made on March 31st.

### NEW RECORDS OF FLIGHT WITH PASSENGERS.

On the 5th ultimo Henry Farman broke all records of flight with one or more passengers by carrying Mr. Hevardson, of the Daily Mail, and Mme. Frank for 1 hour, 2 minutes and 25 seconds. The performance was accomplished with a new and smaller biplane than he has been in the habit of using. Just a month later, on the 8th instant, Daniel Kinet, a Belgian, broke the world's record for flight with one passenger by flying 2 hours and 20 minutes at Chalons. This record was also made with a Farman machine.

### A NEW CROSS-COUNTRY RECORD.

Emile Dubonnet, on April 3rd, won the 100-kilometer (62-mile) cross-country flight prize offered by La Nature. He made a fine flight from Savigny-sur-Orge to Forté-St. Aubin (about 68 miles) in 1 hour and 50 minutes.

### EFFECT OF A PROPELLER BREAKING IN FLIGHT.

While practising at Pau with his Blériot monoplane on the 26th ultimo, Leblanc had a narrow escape. He was at an estimated height of 900 feet when his propeller broke and flew off. Quickly stopping his motor, Leblanc skillfully glided to earth amid the cheers of the spectators.

## The Ascent of Mount McKinley.

Three months ago, a party headed by Thomas Lloyd left Fairbanks, Alaska, for the purpose of climbing Mount McKinley. The summit was reached on April 3rd, after a month of steady climbing. A camp was established at the base of the peak in March. The companions of Thomas Lloyd were W. R. Taylor, Charles McGonigle, and Daniel Patterson. Six other men were also included in the party, but they were left in care of the four camps established on the way toward the top of the peak. Up to 12,000 feet the ascent was easy, but the next 4,000 feet were climbed only by hewing steps out of solid ice. When the 16,000-foot level was reached, a final push was made by the four men named, with success. The expedition had its inception in the violent controversy which raged when Dr. Cook was lecturing. To settle the point whether or not he ever climbed the mountain, and to prove that it could be done, an expedition was financed by August Peterson and William McPhee. No trace of Dr. Cook's ascent could be found on either of the two peaks which constitute Mount McKinley. No records of his were discovered.

Various estimates have been made of the mountain's height. W. A. Dickey, an American prospector, estimated it at 20,000 feet, and gave the peak its present name. Robert Dunn, who made four attempts to climb the peak, estimated its height at 20,300 feet.

Inasmuch as the present party was not properly equipped to measure the height of the mountain, its achievement is not of much scientific value. Fortunately Prof. Herschel C. Parker of Columbia University has expressed his intention of climbing the peak regardless of Lloyd's success. Dr. Parker will approach the peak from the southern side, and will study the glacier and various phenomena. He will take with him scientific instruments, by the skillful use of which undoubtedly more information will be obtained than could be secured by a party of four unscientific but hardy explorers.

Barrill, the guide who exposed Cook, is inclined to dispute Lloyd's claim.

## A New Way of Lighting Stages.

A new system of electric lighting for theater scenes was tried not long since at the Imperial Opera of Berlin, and, it is stated, with great success. It is the invention of the Spanish engineer, Fortuny, and uses an arc lamp as the source of light. The rays of the lamp, instead of falling directly on the scene, are thrown against a series of silk bands which are unrolled and set in any position by means of pulleys. The bands serve to reflect the light and change it into a perfectly diffused light. The new method also includes a sky which is formed in a quarter of a sphere and composed of a steel cap which is treated with a dead white coating. The diffused light is sent into this dome and gives the illusion of an unlimited space. Another interesting device is used to dispense with the ordinary clouds which always have a rigid appearance to the audience. These now appear to be quite plastic and mobile. Such result is secured by the use of mirrors which reflect painted screens representing the clouds. When the mirrors are rotated slowly, the clouds appear to slowly move over the sky. All the present system is worked from four small cabins which are placed in the auditorium. Competent persons are of the opinion that the present invention forms a considerable progress from an artistic as well as a technical and economical standpoint.

# An Automatic Projecting Lantern with Electrical Control

BY JACQUES BOYER

Hitherto it has been necessary for a lecturer using lantern illustrations to employ an assistant to operate the lantern and insert each slide at the proper moment M Moulin has invented an automatic lantern (Fig. 1) which dispenses with the services of the assistant. The ingenious mechanism which inserts and removes the slides can be adapted to any projecting lantern and enables the lecturer, by pressing an electric button on the platform, to show any picture at will The invention will be especially serviceable to teachers, as is shown by Fig 4 The pictures can be thrown on the white wall of the class room, and if a powerful source of light is employed it will not be necessary to darken the room to an extent sufficient to prevent the taking of notes or the use of the blackboard

The lantern slides are attached to a conveyor, composed of two chains connected by grooved cross-bars, which pass over a skeleton drum, formed of two iron disks connected by six rods Each slide is firmly held between a fixed and a movable bar of the conveyor by

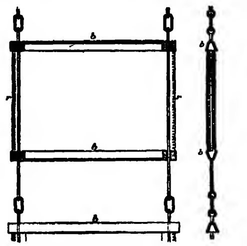

Fig 2.—Front and side views of chains carrying slide holders

the tension of the spring $r$ (Fig 2) The drum is turned by a small electric motor, by means of a tangent screw, and, as it rotates, the slides are brought successively opposite the projecting lens In this operation the flexible conveyor carrying the slides is taken up from a box behind the drum and delivered to a receiving box beneath the lantern

The motor is shunt wound, so that it can be reversed by reversing the current in the armature coils. In this way a slide which has already passed the lens can be brought back and projected again, if desired The electrical connections by means of which the apparatus is controlled are shown diagrammatically in Fig 3 Beneath the lecture table is a switch $I$, the closure of which sends a current through the electric arc $A$ of the projecting lantern, and also through the field coils $S$ of the motor, which are connected in parallel with the circuit containing the arc and its rheostat On the table are two double contact keys $a$ and $a'$ The upper contacts of these keys, 1 and 1', are connected with one wire of the general circuit, the lower contacts, 2 and 2', are connected with the other wire, and the fixed ends of the keys are connected, respectively, with the two brushes of the commutator attached to the rotor or armature $R$ of the electric motor. Hence, when neither key is depressed, both brushes are in connection with the same main wire, and no current flows through the rotor $R$, which consequently, remains motionless By pressing the key $a$, the current is sent through the rotor circuit in the direction indicated by the arrows, and by releasing $a$ and depressing $a'$ the current and the rotation of the motor are reversed The incandescent lamps $L$ and $L'$ are bridged on the

Fig. 1.—An automatic projecting lantern.

keys to diminish sparking but they also serve another useful purpose When the key $a$ is partially depressed, so that it does not touch either contact, the rotor circuit is completed through the lamp $L$, which greatly increases the resistance of the circuit, and the current flowing through the rotor is further diminished by more than one-half by the shunt effect of the lamp $L'$ Hence, the motor turns so slowly that it is an easy matter to stop the desired slide exactly in front of the lens, by releasing the key $a$ at the proper moment. Neither of these effects is produced when the key $a$ is fully depressed, because the lamp $L$ is then short circuited by the key and the resistance of the circuit is thus made so small that very little current is diverted through the other lamp A slow movement of the motor and the slides in the reverse direction is similarly produced by partially depressing the key $b$

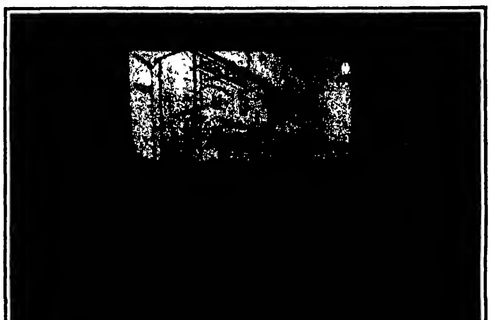

Fig. 4.—A lecture illustrated by the automatic projector, controlled by the lecturer himself.

AN AUTOMATIC APPARATUS FOR PROJECTING PICTURES.

### Tides at Panama.

The average time of high water at places on the Pacific coast of the Central American isthmus is three hours after the moon's meridian passage at Panama The average time of high water at Colon is six minutes, and at Greytown one hour after the moon's meridian passage at Colon In other words, as Colon and Panama are nearly on the same meridian, it may be stated that high tide will occur at the Pacific or Panama end of the Panama Canal, on the average two hours and fifty-four minutes after high tide at the Atlantic or Colon end, and high tide will occur at the Pacific or Brito end of the Nicaragua Canal route two hours after high tide at the Atlantic or Greytown end

The level of mean tide is practically the same at both ends of both of these isthmian canal routes, but at Panama the tide ranges from 10 feet above to 10 feet below mean sea level, while at Colon it only ranges from 6 or 8 inches above to 6 or 8 inches below

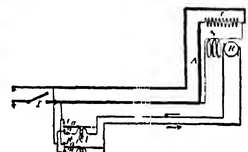

Fig 3.—Electric wiring for automatic projector.

mean sea level, and at Brito or San Juan del Sur the tide ranges in the extreme from 4 feet above to 5 feet below mean sea level, while at Greytown it ranges less than 5 inches above and below mean sea level

Thus with a sea level canal built along either the Nicaragua or the Panama route, there would be through currents from the Pacific to the Atlantic at the times of high tides at the Pacific terminal, and from the Atlantic to the Pacific at the times of low tide at the Pacific terminal

In answer to the specific question Assuming that the Pacific tide rises about 8 feet suppose it to be high tide at San Juan del Sur, Nicaragua, at noon standard time, what would be the approximate difference in level of the Atlantic at the same time say at Greytown Nicaragua?" It may be stated that at the time of high tide at San Juan del Sur it is two hours after high tide at Greytown, and if the assumed rise of 8 feet at San Juan del Sur is above mean sea level the difference in level between the two ends of the canal would be about 7¾ feet.

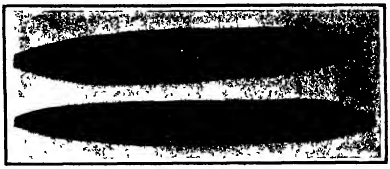
To secure accurate information with reference to the weather conditions Dr William Shaw Director of the Meteorological Office of Great Britain, has been traveling in western Canada With reference to the alleged general changes in the climate owing to the settlement of the country Dr Shaw is skeptical He states that he has observed that the people of all localities are under the impression that the climate of their district is undergoing a change The statistics do not however bear out this idea There are oscillations but no permanent changes in the climate

# INSECT PESTS IN HOUSE AND STORE

BY HAROLD BASTIN

Insects as a class feed literally upon anything and everything from which nourishment may be extracted by dint of strong jaws backed up by equally strong digestions. A substance may be "bone dry," almost as hard as rock, and in every way uninviting, yet so long as its origin is traceable to the animal or vegetable kingdom at least one insect, probably very many kinds, will find in it the wherewithal of existence. And because they are omnivorous in the fullest sense of the word, insects rank as the worst pests with which civilized man has to contend, whether his calling be that of a producer or a disseminator of the necessities and luxuries of life. Much has been written respecting the depredations of insects. Everyone will probably know something at least of the tax which has been imposed upon the exchequer of this country by such insects as the Colorado beetle and the "scale" of the orange groves. But it is with certain pests which, while less devastating in their activities, affect closely the individual comfort of our readers that the writer proposes briefly to deal in this place. Probably few people realize what a number of insect pests are to be found in the ordinary house or larder. Insects penetrate the very fabric of our dwelling places—that is, so far as the woodwork is concerned. They burrow into our furniture and our books, and consume by slow degrees the very carpets on our floors and the clothing in our closets and presses.

Among the most widely distributed of these domestic pests are certain tiny beetles of the genus *Anobium*. Their ancestral home was in the woods and lanes where they are still abundantly represented, frequenting the dead branches of trees and shrubs. They have, however, forced an entry into almost every old house in the land, as well as into many a modern dwelling, where they accomplish considerable mischief by boring into and consuming furniture, beams and woodwork in general. This successful assault of our houses must have been accomplished many centuries ago, for one of the commonest species was dubbed '*domesticum*' by the old naturalists and is so called at the present day. This insect is barely one-sixth of an inch in length, gray brown in color, cylindrical in shape, with its head hidden in, or overhung by, the thorax. The tiny grubs are soft-bodied, with hard heads and—as their work bears witness—powerful jaws. It is not difficult to detect the presence of these grubs in woodwork. Suppose that you have a valuable Chippendale chair, and that you notice beneath it upon the floor, certain little heaps of yellowish dust. Inspection of the chair itself reveals minute holes scattered about the surface of the woodwork—much as though the piece of furniture had been "peppered" from a distance with a charge of dust-shot. These signs are indisputable evidence that your chair is beetle-riddled, and unless by some means you can contrive to dislodge the pests, they will slowly but surely reduce the woodwork to dust and chips.



Cigars damaged by the tobacco beetle.

When once a piece of furniture is assailed by *Anobium*, it is a very difficult matter to eradicate the pest. Several methods have been suggested. One plan is to place the piece of furniture in a refrigerating chamber for a week or two, and thus attempt to kill the beetles and their grubs by cold. It is somewhat doubtful, however, whether even this severe ordeal will destroy all the beetles. Another way, and probably a more effectual one, is to place the furniture—first taking it to pieces if necessary—in a hot chamber or oven, and there bake it for twenty-four hours or more. If the temperature be kept a little above that of boiling water, not a single beetle will be alive when the baking is over. Often it would be impossible to adopt either of these methods, and in such cases the best plan is first to place the piece of furniture in a very hot room for some hours, then to inject, by means of a very fine-nosed syringe, a poisonous liquid—such as creosote or cyanide of potassium—into as many of the tiny "worm holes" as can be found on the surface. Then remove the furniture at once to a cold place, when the sudden change of temperature will cause the poisonous fumes to be drawn into the innermost recesses of the burrows. Finally, the holes on the surface should be stopped up with paraffin wax.

Dust from the borings of the cork-caterpillar on a bottle-neck

Wine bottle cork showing the burrowings of the cork-caterpillar

The various species of *Anobium*, and their bigger relatives of the genus *Xestobium*, by no means confine their attacks to furniture. The whole woodwork of old houses has been so completely riddled by their borings as to render the structures unsafe. Indeed, a beam that has been tenanted by these insects for a number of years is little better than an outer shell containing a mass of wood-dust. A photograph showing damage done to woodwork is here reproduced. *Xestobium*, by the way, is the common "death-watch," while *Anobium* also is in the habit of making a tapping sound. The nocturnal tapping of these insects, distinctly audible in a room where there is an otherwise complete absence of noise, has for many centuries been regarded by the superstitious as a warning of the approach of death. This uncanny interpretation of a mysterious sound is scarcely surprising when we remember that only in recent years have naturalists discovered its true cause. The little beetle has been found in some secluded spot, jerking its hard head at regular intervals upon the surface of the wood beneath it. So far as can be told, its rappings constitute a kind of courtship ritual. Obviously they have no connection with the latter end of mankind. So that the old "death-watch" theory has been exploded!

While speaking of these beetles, the writer may mention another insect known as the "book-louse." It is very minute, soft, and wingless. Its color is that of pale amber, while it is not distantly related to the "white ants" of tropical countries. *Atropus divinatoria*, to give the book louse its scientific name, is very common in old houses, especially if they are damp. As its popular name indicates, it may be found among old books and manuscripts, where it seems to browse upon the surface of the paper. It has also been known to damage collections of dried plants and in-

## FIRE-PROOF CONSTRUCTION AND OUR ANNUAL FIRE LOSS.

It is estimated that our annual fire loss, and the sum expended for fire protection, etc., represent an annual sum that is approximately equal to the cost of building the Panama Canal The public is awakening to the economic significance of this fact, and business men generally are beginning to realize that the best way to guard themselves against the fire peril is, not so much to institute elaborate means for extinguishing fires and burden themselves with heavy insurance, as to so erect their buildings that it will be difficult for a serious fire to originate, and, if it does, impossible for it to obtain a serious hold upon the building The growth in favor of fireproof construction has been indirectly stimulated by the growing price of lumber, the advance having been so great that for some forms of construction there is but little extra initial cost involved in putting up strictly fireproof construction. Indeed, from an investment standpoint it can be demonstrated that the fireproof building is the only really economical building The saving in the cost of insurance, reduction in depreciation charges, the guarantee against interruption of business by fire, combine to make an unburnable building the cheapest in the long run

The phenomenal development in reinforced concrete construction must be regarded as one of the most significant movements in the broad field of architecture and engineering It is not too much to claim that the lion's share of improvements in this direction is to be credited to American engineers The experimental work on sample structural members, and especially upon beams and columns, has led to a pretty thorough knowledge of the true principles of construction to be adopted for reinforced concrete when used in such members, and the introduction of a reinforcement designed to adequately take up the shearing strains, as supplied for instance in the Kahn system, has made it possible to produce beams, girders, stringers, and other members subject to bending stresses, whose strength can be determined with dependable accuracy.

Side by side with the development of reinforced concrete members, such as are suitable to what might be called the skeleton frame of concrete building, much experimental work has been done in producing a suitable form of walling or paneling, for filling in the broad open surface represented by the wall spaces, the floors and the roofing. In the accompanying illustrations we show what is known as the Hy-Rib method of steel sheathing, which is an interesting case of development along this line. It consists of a special steel lath stiffened by rigid high ribs, both the ribs and the lath being made from the same sheet of steel The object of the ribs is to give sufficient stiffness and rigidity to the lath, so that when used in walls and partitions no studs, such as are required by the ordinary plain lath, will be necessary When it is used as reinforcement for floor and roof slabs, no wood centering or falsework is required, for the ribs give the required stiffness. If this sheathing is used for partitions, it is merely necessary to provide a fastening at the floor and the ceiling. The sheets are then set in place and the plaster applied directly to both sides.

For sidings of factories and similar one and two-story buildings, a framework of steel or concrete is provided to which the sheets are attached Lines of supports are provided, about six feet apart and the Hy Rib is properly fastened to them The framework is similar to that which would be provided where the ordinary wood sheathing or corrugated iron is used, except that the girts can be placed a greater distance apart. When the steel has been properly placed a special stucco plaster is applied in two coats

Where the system is used in connection with floors and roofs, supports are ordinarily provided about five feet apart. The sheets are laid directly over the supports with the lath face downward All that is necessary to complete the work is to put in the concrete on the upper sides of the sheets to the required thickness. Only a sufficient amount of concrete will flow through to give a thorough clinch on the steel This leaves a roughened surface on the underside, which provides a satisfactory key for the plaster applied on the ceiling below By use of reinforcing materials similar to this, nearly every type of building no matter how small, may be built fireproof at a cost very little greater than the ordinary wood framing

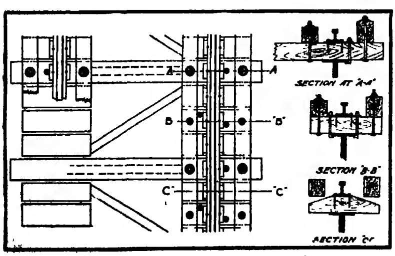
Applying the plaster to a rib-stiffened steel lath and plaster partition.

Building a roof of reinforced concrete construction.

FIRE-PROOF CONSTRUCTION

## IMPROVED ELEVATED RAILWAY CONSTRUCTION

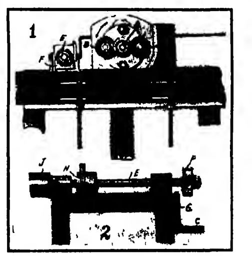
The combination cross tie and "block" the construction shown in the accompanying drawing has for its object to reduce the noise of elevated railroads and increase the light to the street below An open construction is provided yet the rails have an almost continuous support which tends to absorb and stop the vibration sent out from the rails. Most of the noise from a train on an elevated structure is due to the passage of the wheels over the rail joints and there is no doubt that this noise is intensified by the inefficient support of the rails at such points. Should the three "block" ties be removed, letting the rail free of support, and a wheel be rolled over the rail, the vibrating noise would be very great By inserting "block" ties between, this noise is decreased in proportion to the number of ties inserted until when a continuous support is made the noise is reduced to a minimum It is but natural for engineers to copy precedents, and for this reason the usual system of cross ties, which, by a process of evolution, has been found most satisfactory for a road constructed on the ground has been adopted for elevated railroads, with the result that an excessive amount of noise is produced whenever a train passes over the rails, and the street is unnecessarily darkened by the multiplicity of cross ties This proposed system of building an elevated railroad has been suggested by Mr Carl R. Klok, of 1243 Columbia Avenue, Chicago, Ill.



IMPROVED ELEVATED RAILWAY CONSTRUCTION

## ATTACHMENT FOR WOODWORKING MACHINES.

The accompanying engraving illustrates an attachment for woodworking machines generally known as molders or stickers used in sash and door factories for cutting rabbets and moldings in the parts to receive the panels. When a door is to be provided with a pane of glass, it is usually necessary to cut away the molding or rabbet at one side so that the glass can be inserted when the door is completed and be held in position in the usual manner by means of putty In order to avoid a second operation to cut away the molding for this purpose the auxiliary cutter shown in the accompanying engraving is provided The auxiliary cutter is arranged to be moved axially into and out of operative position, so that when it is no longer desired to cut away the molding the operation of the auxiliary cutter can be stopped In Fig 1, which shows a face view of the machine the main shaft is shown at A and mounted upon it is the main cutter head, provided with the cutters B which form the rabbet and molding Immediately in front of the cutter head is a table C on which the work is supported and a pair of guides D for holding the work in position The auxiliary cutter is mounted on a shaft E It consists preferably of a square cutter head provided with a pair of blades F Fig 2 shows a side view of the auxiliary cutter moved to inoperative position so that it clears the work G supported on the table C The shaft of the auxiliary cutter is provided with a yoke and collar H by which it may be moved axially so as to bring the cutter into engagement with the work G The driving pulley of the shaft E is shown at J The inventor of this attachment is Mr A C Tippett of 1283 Franklin Avenue Astoria Oregon

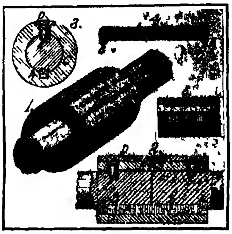


ATTACHMENT FOR WOODWORKING MACHINES

## SHAFT COUPLING

Pictured in the accompanying engraving is an improved coupling of the type adapted for connecting the abutting ends of two revoluble shafts Briefly the device consists of a key and a sleeve which serves to hold the key in place while a second locking key serves to retain the sleeve in position over the two shafts As shown more clearly in the sectional view Fig 2 and in Fig 5, a keyway is cut in each shaft, and a pit or recess is formed at the end of the keyway The shafts are turned so that the two keyways are in alignment and then a key of the form shown in Fig 4, and indicated at A in Fig 2 is fitted into the keyway The key is provided with lugs at the end adapted to fit into the pits of the keyways Before bringing the shafts together, a sleeve C is fitted over one of them This sleeve as shown in the cross-sectional view, Fig 3 is formed with a keyway adapted to fit over the key A when it is moved over the abutting ends of the shafts To hold the sleeve in position, the key D is used This fits into an exterior keyway in the sleeve C and is provided with a pair of lugs E which pass through the sleeve and into the two shafts A screw F serves to hold the key D to the sleeve C In this manner the two shafts are rigidly connected Owing to the large

diameter and massive construction of the sleeve $C$ and owing to the manner in which the two keys are interlocked the coupling has a strength equal to that of any portion of either shaft When the shafts are coupled they are in precise alignment with each other and it is impossible to turn one shaft relatively to the other except by a force sufficient to mutilate them to a considerable extent A patent on this coupling has



A STRONG SHAFT COUPLING

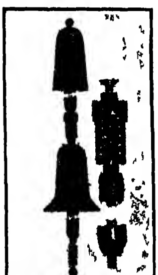
been secured by Mr William F Baum of 2302 Cedar Street Philadelphia Pa

## A NEW SYSTEM FOR HIGH TENSION INSULATION

A patent recently issued to Louis Steinberger of Brooklyn N Y covers a novel and improved system of insulation for high potential electric conductors to be used in various relations and for various purposes such as power transmission and for guy wires or cables employed as stays for towers or poles masts and other supports used in wireless telegraphy and telephony as well as in regular commercial work It marks a radical departure in the development of insulator systems

The system comprehends a series of insulators preferably of a thimble type and a series of other insulators of a rod type the thimble type insulators being alternated with the rod type insulators and together therewith forming a flexible chain of parts which may be extended indefinitely

The under surface of the thimble type insulators will be of course at all times comparatively dry Each thimble type insulator acts like an umbrella covering the upper end of the rod type insulator below it and connected therewith thereby keeping it dry under the most unfavorable conditions (as for instance when all the insulators are subjected to the action of a driving rain) hence the group of insulators must always afford adequate insulation for all practical purposes



A NEW SYSTEM OF HIGH-TENSION INSULATION

This system will practically prevent leakage and undesirable grounding of the current either from conductors or from supporting structures for the same

In this system the various parts may be readily detached and replaced by other parts and the total number of parts may be increased or diminished at will after the original structure is built this feature being especially important in instances where after the installation of a conductor the voltage is to be increased

Not the least important feature of the system is the flexibility of the chain units and that the structure as a whole when in operation is under spring tension thereby insuring more or less resiliency so that the complete structure is relieved in all of its parts as well as in its entirety from the effects of sudden and abrupt accidental strains usually so destructive to mechanism of this kind

## SIMPLE LETTER SCALE.

An inventor has recently struck upon the simple idea of using coins to weigh letters, so that the value of the coin will represent the value of the stamp that must be applied to the letter A simple beam scale is used provided at one end with a clip for holding the letter and at the other end with a clip for holding the coins If the scale is to be used for first-class mail the rates for which are two cents an ounce the fulcrum of the scale is so placed that a letter weighing an ounce would be just counterbalanced by two one-cent coins in the other clip As shown in our illustration the scale beam is made of sheet metal bent to channel form with the ends turned over and terminating in knife-edged pivots on which the letter and coin clips are suspended A detail of one of these clips is shown in Fig 2 It is made of a single piece of metal bent to form two jaws which may be roughened or crimped to provide a better gripping surface At the upper end of the clip are two ears bent upward and provided with apertures to receive the pivots of the scale beam A bail shaped handle serves as a fulcrum for the scale In order to adjust the scale accurately a metal poise is provided on the under side of the scale beam The scale beam is formed of two ears which pass through a slot in the poise and are bent back upon it to hold it in place as indicated in Fig 3 The poise may be delicately adjusted to bring the scale to a correct balance The inventor of this ingenious letter scale is Mr Willis J Fink, of Elk Point South Dakota

## INLET VALVE AND SCREEN FOR PUMPS

The device which is illustrated in the accompanying engraving is adapted particularly for use in con-

SIMPLE LETTER SCALE

nection with water pumps in boats the object being to strain the water that is drawn in by the pump The strainer is provided with a special attachment whereby it may be cleansed instantly while the valve is in service The body of the valve is indicated at $A$ in the illustrations and is provided with a branch $B$ whereby it may be connected with the pump The lower portion of the body is enlarged to form a valve cage $C$ Screwed to the cage is an extension member $D$ which at its lower end is formed with a screen $E$ A valve seat plate $F$ is secured in the chamber $C$ and upon it rests the valve $G$ Lugs $H$ in the top of the chamber $C$ serve to limit the upward lift of the valve $G$ Passing centrally through the valve and casing is a rod $J$ which at its lower end is fitted with a pair of blades $K$ These are adapted to be pressed against the outer

INLET VALVE AND SCREEN FOR PUMPS.

surface of the screen $E$ under tension of a coil spring $L$ By rotating the rod $J$ the blades $K$ are caused to scrape the screen $E$, and thus remove any dirt that might clog the openings of the screen. Mr Olof H. Lillyman, of Potlatch, Idaho, has just secured a patent on this improved inlet valve and screen

## THE INVENTOR OF DIVING ARMOR

Among pioneer inventors to whom the diving dress in its present perfected form owes so much, was William Hannis Taylor The previous "hit or miss" attempts were superseded by the Taylor patent of June 20th 1838 (No 578) in which the essential feature was the valve allowing the emission of consumed air without an influx of water Previous to this time there had been the diving chests and the diving bell of which the latter introduced by Smeaton in 1778 was the safest and most practical device for submarine exploration The diving bell has been developed alongside of the diving dress and is still in use

FIRST DIVING ARMOR.

The general appearance of Taylor's diving armor was like that of a knight's suit of mail except for a prominent bulge in the body piece A large pipe coming down from the surface and penetrating the body piece at the bulge supplied the fresh air while a short pipe entered the body piece on the other side and was provided with a valve which carried off the exhaust Although diving armor has now reached its perfected state this valve has never been materially improved upon The accompanying illustration is reproduced from Mr Taylor's patent

## AN IMPROVED TOBACCO PIPE.

The principal objection to a tobacco pipe as every smoker knows lies in the fact that nicotine accumulates to such an extent as to partially clog the stem and detached particles of the distasteful drug are apt to be drawn into the mouth The saliva is also apt to flow into the stem and collect there To obviate these disagreeable features of the ordinary stem many inventions have been made designed to trap the saliva and the nicotine The accompanying engraving illustrates one of the latest inventions along this line The pipe bowl is provided with two openings one above the other and these are adapted to communicate with two channels in the stem The stem is provided with a core piece in which the channels are formed The core is indicated in the cross sectional view Fig 2 and is shown in full in the large view Fig 1 The upper channel extends the full length of the core and through this the smoke is drawn Near the inner end of the stem the core is provided with several ducts extending downwardly and rearwardly to the lower channel of the core so that any nicotine or solid and liquid particles drawn up with the smoke will be trapped by the ducts and will accu-

AN IMPROVED TOBACCO PIPE.

mulate in the lower channel It will be observed that the lower channel does not extend the full length of the core, so that it is impossible to draw any of the nicotine into the mouth At the opposite end of the core a chamber is formed in the bottom of the core piece which communicates with the smoke channel near the mouthpiece This serves to trap the saliva that may enter the smoke channel The stem of the pipe is jointed near the center so that the outer section may be removed and the core piece withdrawn for the purpose of cleansing it. The inventor of this improved pipe is Mr George Bradley, of 918 Boone Avenue, Spokane, Wash.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

GARMENT RACK.—G. M. VAIL, New York, N. Y. This invention refers more particularly to a rack which can be folded into a compact form, which has hooks for use in supporting garments and like articles, and can be arranged in a plurality of positions, operative and inoperative, and which includes suitable means for supporting the rack from a nail or the like.

### Electrical Devices.

THERMO-ELECTRIC FIRE-ALARM.—G. BLACKHALL, Toronto, Canada. This alarm is especially useful in buildings, such as factories or warehouses, for the purpose of giving an alarm in case of fire. It is also intended to be used in the holds of ships or in other situations where a local rise in temperature may be utilized to indicate the existence of fire.

CARBURETER AND CONTROLLER FOR INTERNAL-COMBUSTION ENGINES.—J. L. TATE, Jersey City, N. J. In the present patent the invention is particularly applicable to systems in which an internal combustion engine is employed for driving a generator and the current from the generator is used for operating a motor or for doing any other suitable form of work. Such a system is illustrated in a prior application for a patent filed by Mr. Tate.

ELECTRIC CUT-OUT.—P. T. MCNALLY, Mandan, N. D. The invention relates to devices for operating at a distance, electric switches in branch lines of electric circuits whereby the current may be cut in or out in said branch lines either from the power house or any remote station thus controlling the current on said branch lines without cutting off the current in the main line leads.

TELEGRAPH INSTRUMENT.—W. McL. JACKSON, Gastonia, N. C. The main object here is to provide means whereby the dots which are used in the ordinary Morse telegraph code, may be made by the single pressure of a key, thereby doing away with the staccato movement of the finger of the operator. Long continued use of the movement causes the finger and hand of the operator to become fatigued and often results in telegraphers' paralysis.

### Of Interest to Farmers.

TREAD MOTOR.—P. W. PETERS, Woodland, Wis. In this case the aim is to provide a smooth and easy running device provided with a gate which may be opened and closed to permit the ingress and egress of the draft animal and wherein the act of opening the gate will lock the wheel from movement.

MACHINE FOR GATHERING COTTON.—W. W. FISH and K. F. CAMPBELL, Jual, Texas. The aim in this improvement is to provide features of construction for a cotton gathering machine, which enable the removal of cotton burrs containing ripe cotton from the plants directly into a receptacle as the machine is moved along rows of cotton plants in a field where they have grown.

### Of General Interest.

MOLD.—P. H. ALLISON, Torrington, Conn. This mold is for use in casting ingots such as brass bars, to be subsequently rolled into sheet or other form. It is capable of being opened and closed without taking up much floor space and arranged to prevent the formation of fins and to allow convenient and quick removal of the casting irrespective of any change in the members of the mold owing to expansion and contraction.

TRUNK PROTECTOR.—E. N. THAIN, Franklin, Mass. The protector is such as used in connection with trunks, boxes and other receptacles for the protection thereof and each of which in general includes a number of corner guards adjustably connected to one another by means of tie members, whereby an upper and a lower frame are formed, and adjustable means joining the frames to hold them in position on a receptacle.

UMBRELLA.—R. L. SUSEMIHL and T. SUSEMIHL, New York, N. Y. An object here is to provide a folding umbrella, which can be disjointed and folded into a compact form, which takes up but very little space, which is easily manipulated both in opening and closing and folding the umbrella and which is strongly constructed so that sudden gusts of wind or the like cannot easily injure or disarrange the frame.

INDEX OR DIRECTORY.—D. T. O'SULLIVAN, West Orange, N. J. In the present invention the improvement has reference to indexes or directories having alphabetically arranged words or names. The object is to produce an index or directory having means for facilitating the finding of any name which is sought, and which will relieve the mind.

FILE-CABINET.—W. J. BALL, Alanreed, Texas. The purpose of the inventor is to provide an accounting device for use in retail stores and like business places which transact business with a large number of customers each day which may be easily understood and operated, and which will eliminate a large amount of unnecessary book work, while at the same time preserving a correct account of each and every transaction.

### Hardware and Tools.

STENCILING AND MARKING POT.—T. F. ADDISON, New York, N. Y. This pot is for use in holding inks and other substances which can be easily manipulated, which is so constructed that the ink can be easily taken up upon a brush or other device used in stenciling and marking in painting, and for other purposes in which the ink is prevented from settling and which has means for freeing the brush from excess quantities of ink.

FISHERMAN'S NEEDLE.—W. J. MAY, New Orleans, La. The object here is to produce a needle such as used by fishermen for repairing nets and seines and having a special construction including a knife which can be readily operated when desired. Under normal conditions the edge of the knife does not protrude from the body of the needle so that the blade is held in an inoperative position.

VALVE OR FAUCET.—E. P. MCCOLLOM, Baltimore, Md. This device is intended more particularly for embodiments in faucets used in connection with a filter the bottom of which seats on the chambered top of the faucet. The valve in the faucet coacts with a novel arrangement of ports and passages for directing the water from the supply pipe through the filter or merely against the bottom of the filter to wash the same and then directly through the faucet; or the valve may be so turned as to cut off the supply pipe and drain the filter.

STAMP AND LABEL AFFIXER.—G. E. LACEY, Lansing, Mich. The invention pertains to a device to be used in affixing stamps or labels to letters or articles of manufacture. One object of the invention is to provide a device which will automatically grip a label or stamp and dispose it in proper relation on the surface to which it is to be affixed.

DOOR AND DAMPER OPERATOR.—J. LAUS, JR., Oshkosh, Wis. The invention is an improvement in door and damper operators and the object is to provide a spring operated mechanism normally restrained from action for opening and closing, the dampers and doors of a furnace or the like at a predetermined time which mechanism is released by a clock movement.

### Heating and Lighting.

WATER HEATER.—J. W. HARRIS, Sourlake, Texas. This device is for use for heating feed water in oil or gas burning boiler furnaces. The invention has reference to improvements in feed water heaters and has for its object the provision of an improved apparatus for the rapid and economical heating of water for steam purposes in oil and gas burning boilers.

### Household Utilities.

FLY EXIT.—L. W. CLARK, Carterville, Mo. The object here is to provide a device of low cost which may be applied to the ordinary window screen with but little cost or trouble and which will permit flies free egress from the room or building, while at the same time effectually preventing their ingress.

PORTABLE FLY CATCHER.—C. H. PEAKE and L. P. TEUSCHER, Aspen, Colo. In this instance the invention relates to improvements in portable means for catching flies. The invention has for its object the provision of a device by the use of which the flies in a house or dwelling may be removed quickly and effectually, while at the same time obviating all of the disadvantages of foregoing methods.

### Machines and Mechanical Devices.

MACHINE OR APPARATUS FOR PRINTING, CHECKING AND AUTOMATICALLY SUMMING UP THE VALUES OF TICKETS OF DIFFERENT KINDS AND SERIES.—G. F. BOULADE, 44 Rue Chanzy, Paris, France. The invention provides a small portable machine for use in printing and checking tickets of different classes and kinds and for automatically adding up corresponding receipts. It effects by a single operation first the impression upon each ticket of the date, destination, price, route and number of days available. Second, the simultaneous impression upon a checking sheet of all data placed on the ticket. Third, the automatic adding up of the sums collected.

STREET-GAGE.—P. ROUGHEN, Fond du Lac, Wis. This device detects inequalities in grading of street pavements, mechanically adjusts the height of the crown of the paved street, is movably and guidably mounted on the street to be readily shifted over its surface and is capable of being adjusted to varying street widths.

TYPE WRITING MACHINE.—N. F. PETIT, Charleston, S. C. Among the principal objects in view in this case are: To provide a construction to occupy a minimum of space; to provide an arrangement of type wherein a number of characters may be arranged to be employed; and to provide a portable machine which is simple, economical and durable in construction.

COMBINED BALL AND TUBE MILL.—J. E. KENNEDY, New York, N. Y. This mill is adapted to comminute ore, cement or the like from a comparatively large size to a fine powder. It is adapted for use in wet or dry crushing and consists primarily in a tube chamber in which crushing is done in two stages. It performs in one machine that which formerly took two to accomplish.

DRILLING-MACHINE.—G. MCKNIGHT, Townsend, Mont. This machine affords a positive manually controlled feed for the drill, and facilitates its withdrawal from a bored hole when desired, and also provides reliable means for detachably securing the drilling machine upon an object that is stationary or has sufficient weight to afford proper support to the machine when in use.

STATION INDICATOR.—F. K. HARRIS, Canandaigua, N. Y. The indicator is intended for use in passenger cars or other vehicles for indicating the next station at which the car or vehicle is to stop. More particularly the invention relates to that type of station indicator in which there is provided a long band or curtain bearing the names of the successive stations and movable to bring successive portions to view.

WIRE FENCE MACHINE.—D. A. CLAWSON, Waynesville, Ill. This machine is for use in making wire fences in the field and arranged for ready attachment to the line wires of the fence to properly guide or hold the stays while attaching the same to the line wires, and to permit ready attachment of the machine to the line wires to allow the operator to accurately fasten the stays in proper vertical position to the line wires.

KEG RINSER.—A. C. LA BUDDE, Ashland, Wis. The invention consists of a water supply conduit having a nozzle and a controlling valve, a foot lever operable to simultaneously project the nozzle valve into the keg and open the valve, and rollers to support the keg over the nozzle, each roller tapering toward the center to conform to the keg and facilitate its movement to rinsing position.

LUBRICATING ATTACHMENT FOR WINDING MACHINES.—S. BROADWIN, New York, N. Y. The invention relates to applying a lubricant to yarn thread or the like in being wound onto a spool bobbin or spindle. The object is to apply it to the thread after it is wound on the bobbin or the like, the lubricant preferably being in solid form and held against the sides of the several windings on the bobbin as the latter rotates.

SCALE.—A. F. JOHNSTONE, Cleveland, Ohio. The invention provides a scale having a pouring attachment to deliver only when the scoop is in receiving position, a pouring attachment adjustable above the scale platform, a locking attachment for the scale beam to prevent the flow from the pouring device except under conditions, a pouring attachment to handle plastic and dry materials with spout openings, and an electrically operated mechanism for terminating the delivery from the pouring device when the desired weight has been obtained.

### Railways and Their Accessories.

MAIL BAG CATCHER AND DELIVERER.—C. E. HASTINGS, Vernon, N. Y. This is a device adapted to receive mail or other packages from and deliver mail or other packages to a moving train from a stationary platform. An object is to provide a device which will suspend the mail bag or other package in a locked position until a trigger is tripped by opposing mechanism.

RAILWAY CAR BRAKE.—L. BOIRAULT, 8 Rue Émile Gilbert, Paris, France. The invention consists in making use of the tire force of the car to produce the application of the brake in such manner that when the system of operating levers has been brought by hand or through gearing into a determined position a cam operated by a car axle actuates the system of levers and produces the application of the brake blocks to a determined extent and locking them in braking position.

### Pertaining to Recreation.

DANCING DOLL.—A. M. LARSTON, Hoxton, Ga. In this instance provision is made for disassembling and packing the separated parts in the stand; for a construction whereby the doll is manipulated to simulate the movements of a dancing person; and for a construction for a doll which is simple, efficient and the wearing parts whereof are rapidly and easily replaced.

### Pertaining to Vehicles.

TIRE TREAD.—H. T. O'SULLIVAN, West Orange, N. J. An object of this invention is to provide a tread having a form which facilitates its attachment to the wheel without producing a puckering of the material at the sides of the tread. Also to provide means for securing the tread to the spokes of the wheel which will prevent slipping and longitudinal slipping of the tread on the tire.

PORTABLE PRISON.—J. B. KIMBELL, Cordele, Ga. This invention is applicable to vans for use in transporting convict laborers. Heretofore they have been carried in confined quarters. Considerable inhumanity has resulted from the too close confinement during leisure such as after working hours and on Sundays and holidays in which this class participate. The chief purpose is to overcome the above disadvantages by forming a single detention room or house.

VEHICLE-TIRE.—H. B. TOMAS, Hoboken, N. J. The invention comprises the combination of a rim cushions mounted thereupon, a composite member having generally an annular form encircling the rim and with portions engaging the cushions, a plurality of members arranged in a general annular form and connected to the composite member, the last members overlapping one another, and a tread supported upon the last mentioned members.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention and date of this paper.

## INDEX OF INVENTIONS

### For which Letters Patent of the United States were Issued for the Week Ending April 12, 1910,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Abdominal retractor, J. F. Sparks ... 955,006
Abrasive material and making same, H. [illegible] Saunders ... 954,766
Acoustic apparatus, Hapburgh & Borsyth ... 954,715
Advertising apparatus, rotating, [illegible] ... 954,525
Advertising device, A. Marks ... 954,752
Advertising device, W. M. [illegible] ... 954,765
Advertising device, J. A. [illegible] ... 954,842
Airship, [illegible] ... 955,080
Alarm apparatus, J. K. Hull ... 954,675
Alfalfa pellets, feeder for, W. Sikes ... 955,000
Aluminum and titanium, composition of matter containing, A. [illegible] J. K. Saunders ... 954,767
Aluminum silicon and titanium and making same, composition of matter containing, same, J. F. Saunders ... 954,768
Ambulance, W. von Ottingen ... 954,700
Anchor, ground, [illegible] ... 954,[illegible]
Anchor, strong, N. H. Powell ... 954,882
Anesthetic apparatus, [illegible] ... 955,[illegible]
Animal feeding or delivering machines, feeder arms for, A. Hauenstein ... 954,[illegible]
Animal trap, J. Jackson ... 954,075
Armature winding, F. [illegible] ... [illegible]
Ash pan dumping, J. J. Hudson ... 954,072
Asparagus knife, [illegible] ... 954,[illegible]
Bag fastener, J. S. [illegible] ... 954,[illegible]
Ball, artificial, J. F. Ullinger ... 954,891
Baking pan, I. Wing ... 954,[illegible]
Bale tie making, J. A. Schaff ... 955,090
Barrel cleaning apparatus, S. Kellogg ... 954,814
Barrel heater, H. Crabb ... 954,[illegible]
Bath, [illegible] ... 954,07[illegible]
Bearing, antifriction, A. Poulen ... 954,404
Bearing for pulleys, self oiling, [illegible] M. Whelton ... 954,817
Bearing, roller, [illegible] A. Brewer ... 954,[illegible]
Bearing, self contained roller, [illegible] S. Lockwood ... 954,539
Bearing, self oiling, [illegible] M. Winslow ... 954,830
Bearings, vibration reducer for shaft, [illegible] Cosby ... [illegible]
Bed construction, J. J. Hall ... [illegible]
Bed frame, J. [illegible] ... [illegible]
Beer and the like, apparatus for chilling and carbonating, H. F. Stanley ... 955,108
Belt [illegible] A. Bourbon ... 954,610
Belt guard, J. J. Fisher ... 954,618
Billiard table, reversible, J. N. McIntire ... 954,737
Binders, treating adhesive, J. H. McLaurin ... 954,[illegible]
Blind feeding mechanism, J. F. Abrams ... 955,114
Bleaching agents, apparatus for storing, diluting and applying, J. A. Wessner ... 954,835
Blowpipe, F. L. Melanson ... 955,[illegible]
Blowpipe for welding metal, J. J. Griffin ... 955,064
Boat folding, J. Vaghi ... 954,[illegible]
Boats, device for releasing submarine, [illegible] Spear ... 954,707
Bobbin holder, H. S. Tallison ... 954,[illegible]
Boiler. See Downdraft sectional boiler.
Boiler bottom, H. [illegible] ... 954,[illegible]
Boiler safety appliance, steam, F. Roth ... 954,781
Bolt, N. W. [illegible] ... 954,481
Bolt and latch lock, J. Dore ... 954,[illegible]
Bonded article and making same, [illegible] N. Jepson ... [illegible]
Book retainer for a train, J. [illegible] ... [illegible]
Book mark, [illegible] H. Brooks ... 954,114
Boot and shoe, MacFarland & Baker ... 954,710
Bottle capping machine, J. A. McAnulty ... 954,095
Bottle cooler, H. A. Toppert ... 954,798
Bottle, nursing, H. C. Janes ... 954,[illegible]
Bottles or other receptacles, means for stopping or sealing, H. W. Johnson ... 955,079
Bottles, stopper lock for, J. L. Peters ... 955,080
Bottling machine, A. Schneider ... 954,821
Box, Horton & Cheatham ... 954,676
Box for vials, flasks and similar objects, Barell & Girard ... 955,041
Box lifting machine, W. A. Joplin ... 954,780
Brick handling machine, H. C. [illegible] ... 954,[illegible]
Bricks, composition of matter for the manufacture of building, H. D. Phillips ... 954,[illegible]
Bricks, composition of matter for the manufacture of road or street, H. D. Phillips ... 954,601
Brush, J. L. Koskins ... 955,001
Brush, scrubbing, Raymond & Baker ... 954,[illegible]
Bucket, bottom dumping, O. J. Stanbury ... 954,480
Burner, D. O. Rose ... 954,702
Butter pat making device, F. W. Billings ... 954,608
Button setting machine, C. Hinson ... 954,821
Cabinet for sheet fabrics, storing and dispensing, J. K. Hart ... 954,[illegible]
Can bodies, etc., machine for slitting or trimming blanks for, [illegible] W. Graham ... 954,[illegible]
Can centering and truing device, Kennamer & Taliaferro ... 954,076
Car construction, H. H. Adams ... 954,[illegible]
Car door operating mechanism, [illegible] J. Robbins ... 954,[illegible]
Car, dumping, C. P. Astrom ... 954,[illegible]
Car fender, J. D. Marvil ... 954,[illegible]
Car fender, F. Patsky ... 954,70[illegible]
Car fender, street railway, R. Murphy ... 954,[illegible]
Car, ladle, C. P. Astrom ... 954,501
Car pneumatic door device and brake release mechanism, combined street, Hewstree & Spencer ... [illegible]
Car replacer, H. H. Harrison ... [illegible]
Car transferring device, O. H. Baker ... [illegible]
Car ventilator, R. E. Frame ... 954,500

Cars, automatic registering device for street, L. J. Dugan 954,736
Cars, dirt spreading attachment for, E. McCormick 954,530
Cars, safety controlling device for street, E. D. White 954,710
Carbon remover, R. Kastrow 954,491
Carbureter, A. M. Wolf 954,488
Carbureter, A. Howarth 954,630
Carbureter, H. O. Craven 954,785
Carbureter, A. M. Wolf 954,916
Card dealing machine, R. A. Berger 955,044
Carriage and sleigh combined baby, D. H. Huff 954,681
Carrier. See Lineage carrier.
Cash register, F. H. Trevillian 955,016
Celluloid formate, R. von Kapff 953,092
Cement brick machine, Buckeye & Burstein 954,416
Cement manufacturing, R. Tornay Schosberger 954,658
Cement or concrete fence post, H. W. Underwood 954,831
Cement or concrete fence post mold, H. W. Underwood 954,830
Cement spraying apparatus, N. Marshall 954,763
Chain conveyer, C. W. Hornbach 955,070
Chain drive sprocket, T. A. Edison 954,780
Change maker, I. G. Palmer 954,761
Check controlled manually operated lock, A. W. Higgs 954,700
Chute filter, J. M. Wright 954,662
Chimney, C. Hoefrich 954,570
Churn, H. P. Hyland 955,074
Cigar holder for hats, W. W. Kaltenbach 954,740
Cigar lighter, C. Dinger 955,068
Cigarette cutting machine, continuous, H. Bilgram 955,113
Cigarette packing machine, H. Bilgram 954,917
Circuit controller, R. Cabot 954,716
Clamp, F. E. Kohn 954,524
Clean out fitting, C. Colombo 954,852
Clock synchronizing attachment, J. R. Burns 954,714
Closet bowl or fitting, W. E. Young 954,604
Closet rinsing apparatus, R. Stickdorn 954,609
Cloth's cleaner, H. W. Scott 955,106
Cloth driving, D. S. Beard 954,774
Coal mechanism for feeding pulverized, W. H. Dunn 954,944
Coal screening apparatus, A. W. Crawford 954,685
Coal washing machine, J. A. Montgomery 954,966
Coin holder, F. Holzenstein 954,589
Compasses, P. Hogner 954,895
Composing machine, typographical, Pearce & Billington 954,459
Concrete bridge, reinforced, J. R. Mandeville 954,750
Concrete composition of matter for, H. H. Phillips 954,692
Concrete construction, F. Mellner 954,683
Concrete construction, trussed bar for reinforced, I. Stragiotti 954,800
Concrete construction, waterproof, F. P. Lawrence 954,814
Concrete culverts, cisterns, and the like, adjustable frame for building, W. Prittman 954,696
Concrete structures, reinforcement for, C. Brossman 954,925
Concrete wall, H. N. Pettigrew 954,690
Concrete walls, reinforcing metal yoke for hollow, W. H. Nelson 953,877
Confinement chair, E. P. Schertmann 954,474
Controller, mechanical, H. W. Forslund 954,508
Convertible chair, A. G. Shaw 954,594
Conveyer apron, E. H. Clymans 954,761
Conveyer chute, Snell & Hand 954,895
Cooling system for packing houses, T. Fellows 954,664
Copying device, manifold, A. B. Sampson 954,822
Core box, J. Kraus 954,442
Cores for pipes and other hollow castings, machine for making sand, J. H. McWane 954,876
Cotton chopper, T. H. Ellis 954,566

INSECT PESTS IN HOUSE AND STORE.

(Continued from page 344.)

sects. My reason in mentioning it in this place, however, is that it is said to be capable of making a regular tapping noise which is audible to mankind. Its extremely small size, and the softness of its body, make it difficult to understand how this noise can be produced, but I give the fact on the authority of an eminent observer. Before leaving the boring beetles of the genus *Anobium* mention should be made of the species known popularly as the bread or paste beetle (*A. paniceum*). It is very common in houses and possesses a voracious appetite. Moreover, it cannot be termed "dainty," for it appears to eat almost anything which it encounters, from dry wood to Cayenne pepper, although it seems especially to appreciate bread, biscuits or other concoctions in which flour and water are the chief ingredients. It is often most destructive to the stored goods of merchants, as well as to the stocks of grocers and chemists. Two of the photographs here reproduced show samples (1) of marcaroni and (2) ginger riddled by this pest. I have also known it to feast upon dry capsicums. This insect, too, has rendered almost worthless a stock of boots and shoes which, before the advent of the pest, had been valued at many thousands of pounds. This happened in South Africa, although reports of damage have also been received from manufacturers in other parts of the world. Paste had been used in making the boots, to fasten the linings and leather together, and in devouring their favorite dainty—i. e., the paste—the beetles had perforated and damaged the leather so as to reduce it literally to rags.

The so-called paste beetle, moreover, is probably the worst offender among the insect enemies of books. It gets into old libraries, and its grubs gnaw the edges of the pages and drill their tunnels from cover to cover of the volumes. The photograph reproduced here will give some idea of the serious damage of which this pest is capable, and may stand as a warning to all lovers of "first editions" and other costly tomes. In times past many valuable books have been rendered almost worthless in this manner while there is a case on record in which twenty-seven folio volumes, standing side by side, were perforated in a straight line by one *Anobium* grub or "book worm." Its tunnel was so perfectly drilled that it was possible to pass a string from one end of it to the other, and thus lift up the entire set of twenty-seven volumes at once. These grubs have also been known to tunnel through sheet-lead when this has come in their way, a fact which bears witness to the hardness of their heads and the strength of their jaw muscles.

Probably few people, save those who dabble in natural history, are aware that a small moth—one of the *Micro-lepidoptera*—is held in dread by wine merchants and cellarers in many parts of the world. Large numbers of wine cellars are affected by this pest, and its depredations represent an annual loss which must run into many thousands of pounds. Of course, the moth itself is harmful only as the progenitor of hungry caterpillars. But it appears to have renounced the traditional air-and-sunlight habits of moths in general, and to frequent by choice the gloom of subterranean vaults. Here the female insect lays her eggs upon the corks of wine bottles, and when the tiny caterpillars hatch they burrow into the substance of the cork, just as the caterpillar of the big goat moth burrows into the heart of an oak or an apple tree.

The presence of the wine-cork pest is manifested by an accumulation of cork-dust and refuse ("frass") round the exposed portions of the cork. This accumulation may be seen in one of the pictures herewith. Later, if the grubs are numerous, the cork is so tunneled that the wine escapes—this being the so-called "ullage" of wine. Sherry, madeira and champagne corks are attacked indiscriminately; and even when the corks are not so badly tunneled as to produce ullage, the wine usually becomes tainted, and is thus rendered valueless.

Even new corks in store are sometimes injured by the caterpillars of a moth, though in this instance the taste appears to be a recently acquired one, for the insect in question is really the fig moth (*Ephestia ficulella*). As its name implies, its caterpillars feed normally on dried figs. So prevalent is this pest that it may almost be described as a common object of the dessert table, for few figs, save the most recently imported, are quite free from the small white grubs of this moth. In passing, it may be remarked that this insect is also known to attack cocoa beans.

But while the fig moth accomplishes no small amount of damage, its depredations are far less serious and widespread than those of its relative, the codlin moth. This is another of those insects which come unbidden with the dessert. I am able to reproduce a photograph which gives a good idea of the damage done to an apple by this pest. The reader will observe that the caterpillar confines its attack chiefly to the center of the fruit, where it feeds upon the pips and core. Sometimes a most delicious-looking apple, apparently perfectly sound, proves to be full of rottenness on being cut open. It may be that the reader is wondering how the caterpillar got into the apples, just as George IV is said to have wondered how apples got into dumplings. The facts of the case are as follows: The little codlin moth flies about at dusk in orchards just at the season when the young apples are forming. She visits one fruit after another, and lays an egg in the "eye" of each. When the egg hatches, the minute caterpillar burrows into the heart of the apples, making a hole so small that it is unnoticeable when the apple attains its full size. Thus is provided the phenomenon of a hungry grub consuming the interior of an apple which, to all appearances seems to be as inviting as any of its neighbors.

When the grub is full fed it bores its way out of the apple, and eventually spins a cocoon of rough silk in a crevice in the tree trunk, or on a neighboring fence in which it changes to a pupa. Despite its name, the codlin moth does not confine its attention to any particular variety of apple, but attacks all the best kinds indiscriminately. It has attained a very wide geographical range—having followed the apple tree, so to speak, all over the world. It has called forth the maledictions of apple-growers in France, Germany, Great Britain, Canada, Australia and Tasmania, as well as in the United States. In Tasmania it has been so troublesome that the legislature has thought it necessary to pass an act for its suppression.

Tobacco merchants and manufacturers are sorely tried at times by the activities of a beetle known to science as *Lasioderma testacea*. This insect has acquired the habit of feeding upon stored tobacco. It is especially injurious to cigars and cigarettes. Photographs showing examples of its work are reproduced herewith. Yet another beetle attacks nutmegs, coffee berries, and certain kinds of spices. The annexed photograph shows us a sample of Java coffee, some fifteen years old, almost every berry of which has been bored by this pest. Fortunately the attacks of this beetle do not affect the quality of the coffee when ground. Nevertheless, it is quite certain that when buying old coffee one buys also a certain amount of ground-up beetles—and this fact may be displeasing to many. Yet if one were to avoid food or beverages simply because one doubted their freedom from contamination by insects, one would eat and drink very little indeed!

I doubt if there is a man or woman living who has not eaten—of course, quite unwittingly—very many examples

of the weevil known as *Calandra granaria*. This is one of the most injurious pests with which corn merchants have to contend, despite the smallness of its size. I am able to reproduce a magnified photograph showing a few grains taken from a sample of wheat which had been attacked by *Calandra*. The sample fairly represents the condition of a whole cargo of wheat which was rendered practically valueless during a protracted voyage across the Atlantic. In the case of this one shipload, the loss caused by this beetle amounted to many thousands of pounds, while costly litigation ensued. Of course, an instance of this kind is somewhat exceptional. Nevertheless, the corn weevil imposes a constant tax upon stored grain, while it is no exaggeration to state that every granary is infected by this pest. Thus, countless millions of the insects must be ground with the wheat into flour each year, and the weevils must, therefore, form an actual part of the bread which we eat.

Another corn pest is a small moth which is especially injurious to stored flour. Its scientific name is *Ephestia kuhniella*. It is the scourge of the Mediterranean ports, where it is impossible to estimate the extent of the damage which it accomplishes. In November, 1887, *Ephestia* made its appearance in East London—having been brought thither, no doubt, in ships. Its presence was first detected in a warehouse at the docks. Unluckily, over a thousand tons of flour were stored in close proximity; and, although all possible efforts were made to save it, the insects multiplied with such extraordinary rapidity that the trouble taken was of no avail.

### Buggy-top Canopies for Launches.

Experiments have just been completed by the naval constructors with a view to the adoption of a new type of canopy for use on the naval launches.

When the launch of the U. S. S. "Minnesota" was lost in Hampton Roads with several midshipmen on board about a year ago, the fatality was attributed to the fact that the canvas covering used as a protection against the weather was fastened in such a manner that it could not be quickly released, and the men were hopelessly imprisoned in the sinking boat. This fact led to much criticism of the type of canopy used and the steam launches came to be known as "death traps."

The constructors have been working on a design intended to overcome that difficulty, and several types of canopies were tested on launches of the Atlantic fleet within the last two or three months.

The result of these tests is the adoption of what is commonly known as the buggy-top canopy. This is made of canvas, and is attached to rods in such a manner that the canopy can be easily adjusted and folded out of the way, similar to those used on automobiles.

While the new style of canopy will not be as durable as the old fashioned one, and will not afford the same protection against wind and rain, in case of a collision, and the launch is in danger of being sunk, it can be quickly put out of the way and not endanger the lives of the occupants of the boat.

---

By microphotographic methods, the vibrations in an incandescent filament, due to the expansion and contraction caused by the passage of an alternate current, have been recorded. An arc lamp was used as the source of light for photographic purposes, and if the arc is fed from the same alternator as the incandescent filament, the vibrations are seen from the plate to synchronize with the rise and fall of the alternating pressure. With a 100-candle-power osram lamp, supplied with alternate current at 50 alternations, a slight humming noise was perceptible even at a distance of three yards. The experimenter considers that this may be a cause contributing to the shorter life of a metallic filament on alternate current.

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO. Inc.

## BUSINESS OPPORTUNITIES

A WELL ESTABLISHED FIRM of instrument makers with branches in Europe wishes to market under royalty one patent device instrument or novelty to supplement their present line of business. Apply by letter to T. P. O. Box 773, N. Y.

Inquiry No. 9018. For manufacturers of "Wydt's Electro Catalytic Sparking Plug."

INVENTOR desires reliable financial aid concerning a new motive power for ships, etc. Write only. Von Kiefer, 341 Spring Street, New York.

Inquiry No. 9087. Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

## PATENTS FOR SALE

FOR SALE. U. S. patent automatic time cut off for individual electric lights. Needed wherever electricity is used for lighting. Will submit particulars and samples to those interested. Paul Dixon, 47 Whitehall St., Atlanta, Ga.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

FOR SALE. Patent No. 919,419. Burglar proof sash lock. A fortune can be made from this patent. Price very moderate. Address L. H. Grau, 860 Pine Street, San Francisco, Cal.

Inquiry No. 9019. Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## HELP WANTED

MECHANICAL SUPERINTENDENT to take charge of large machine shop. Apply stating experience and salary expected. Superintendent, Box 773 N. Y.

Inquiry No. 9027.—Wanted to buy silk machines from re-reeling, twisting, doubling to the final process of making it into clothes.

EXPERIMENTAL ENGINEER wanted, by a large manufacturing concern having technical and practical knowledge of mechanics and preferably chemistry as well. Must possess special aptitude for this character of work. Address in confidence with full particulars including salary expected. Business Service Co., 395 Broadway, New York.

Inquiry No. 9029.—Wanted catalogues and all information on machinery for braiding straw in manufacturing straw hats.

## PARTNERS WANTED

WANTED.—Partner to obtain principal foreign patents on improved gas engines. Device simplifies and reduces cost of operation, increases reliability and horse power of engine. Will reduce cost of manufacture 40 per cent. John C. Anderson, Terrell, Texas.

Inquiry No. 9038.—Wanted the address of the Chipman Electric Purifying Co.

## MISCELLANEOUS.

SMALL MACHINES or parts manufactured at low cost. Punch press work, tempering and case hardening a specialty. Joseph Pollak, 21 Sydney St., Dorchester, Mass.

Inquiry No. 9042. Wanted the address of Farney Safety Razor Co.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9058.—Wanted, address of firms who install plants to manufacture nitrogen.

## SALE AND EXCHANGE

FOR SALE. Engine lathe. Our regular $75.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $44.00. L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9065. Wanted address of parties interested in Log Cleaning Machines.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9066. Wanted to buy machinery to manufacture steel coin racks.

Inquiry No. 9068.—Wanted complete outfit for export for making rice flakes and wheat-flakes.

Inquiry No. 9073.—Wanted, machinery to manufacture cocoanut oil; also the crude material.

Inquiry No. 9071. Wanted to buy old model locomotives or steamboats such as were exhibited with nickel in the slot attachments in ferry houses, etc.

Inquiry No. 9075. Wanted to buy small weather vanes such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted the address of parties in Canada who could make a safety razor.

Inquiry No. 9077. Wanted the address of manufacturers that make small articles of wood, such as checker boards, etc.

Inquiry No. 9078.—Wanted the address of manufacturers of sewer pipe, made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9079. Wanted, parties to make a special steel plate rolled for "angle bars," in large quantities.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9083. Wanted the address of firms manufacturing small beer brewing plants, from 75 to 100 gallons a day.

Inquiry No. 9084.—Wanted the address of manufacturers of frame portable bath tubs.

Inquiry No. 9085. Wanted to buy longitudinal hollow perforated tubing.

Inquiry No. 9088. Wanted to buy a pine wood peeler.

Inquiry No. 9090. Wanted manufacturers of suspender and supporters supplies, also patent adjustable bachelor buttons.

Inquiry No. 9092.—Wanted the address of some firms who manufacture permanent lamp wicks.

Inquiry No. 9094. Wanted address of The Thomas Arithmometer Company, also Burkhart Arithmometer Company.

Inquiry No. 9095.—Wanted, name and address of the manufacturer of the duplex revolving pencil sharpener.

Inquiry No. 9096.—Wanted, the address of manufacturers of spiral welded pipes, possessing great strength.

Inquiry No. 9097. Wanted, address of makers of impulse water wheels.

Inquiry No. 9098.—Wanted, name and address of the manufacturers of the ozonizer.

Inquiry No. 9099.—Wanted address of manufacturers of machinery for making wire cables.

Inquiry No. 9101.—Wanted addresses of manufacturers of a dip or magnetic needle, for exploring for iron ore.

Inquiry No. 9104.—Wanted addresses of manufacturers under the name of A. O. Co. Standard.

Inquiry No. 9106.—Wanted addresses of cotton dealers who can furnish cotton material for manufacturing envelopes.

Inquiry No. 9107.—Wanted addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

Inquiry No. 9109.—Wanted addresses of the manufacturers of the Dion Desk Clock.

Inquiry No. 9110.—Wanted to buy machinery for reducing old tin cans, so that they may become a source of revenue.

Inquiry No. 9112. Wanted sample small dry vacuum pump about 6-inch diameter cylinder inside, high temperature metal packing.

Inquiry No. 9113.—Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

Inquiry No. 9114.—Wanted name and address of manufacturer of the Auto Lantern Globe. Fits all lanterns.

Inquiry No. 9115.—Wanted a machine for making pen nibs, similar to Wm. Mitchell's G. & J. nibs and Waverly nibs.

Inquiry No. 9117.—Wanted names and address of the manufacturers of pedometers.

Inquiry No. 9118.—Wanted, a muffler for a gasoline engine, built upon the principle of the Maxim silencer, recently brought out for use on rifles.

Inquiry No. 9119. Wanted, name and address of the manufacturer of Zeglin bullet-proof cloth.

Inquiry No. 9120.—Wanted the address of the Ideal Fuel Feeder Co.

Inquiry No. 9121.—Wanted manufacturers of cut stencils for fancy work, sofa pillows, etc., and oil colors and brushes for same.

Inquiry No. 9124. Wanted name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

Inquiry No. 9127.—Wanted, address of L. Dermigny, manufacturer of a family ice machine for $10.00.

Inquiry No. 9131.—Wanted information as to how or where I could get a sample of tile ore.

Inquiry No. 9132.—Wanted, manufacturers of a gasoline traction engine with a hoisting attachment; in other words, the machine will be used as a portable stump puller to pull sassafras roots, used in making oil of sassafras.

Inquiry No. 9133.—Wanted manufacturers of floss candy machines.

Inquiry No. 9134.—Wanted, a small hydraulic motor capable of giving about one horse power with a water power of 35 lbs. per square inch.

Inquiry No. 9135.—Wanted, name and address of manufacturers of the Parshall Compressed Air Ice Machine.

Inquiry No. 9136.—Wanted the name and address of a skunk raising farm.

Inquiry No. 9137.—Wanted, a device that will braid leather strips for horse whips.

Inquiry No. 9138.—Wanted the address of manufacturers of machines capable of forming a number (12 or more) of pieces of paste about 35 mm. x 25 mm. x 6 mm. made of lead oxide and sulphuric acid, and placing them into a frame having a separate compartment for each piece, the space between each piece and the next being all round 4 mm. The process could be somewhat similar to biscuit making.

Inquiry No. 9139. Wanted, the name and address of some manufacturer of a coffee mill run by water motor.

Inquiry No. 9140.—Wanted, manufacturers of disc records for gramophones that use a sapphire point instead of a steel needle.

Inquiry No. 9141.—Wanted a boat like a rowboat, worked by levers in place of oars which by a series of pulleys attached operates a propeller, the steering device is managed with the feet.

Inquiry No. 9142.—Wanted, an appliance used in ice chests to make ice last longer.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short and the facts authentic the contributions will receive special attention Accepted articles will be paid for at regular space rates

### WHY NOT A GOOD ROADS LABORATORY?

THE problem of maintaining good roads, always a most important one in the United States, has recently been rendered of critical urgency by the rapid development of the automobile—the most destructive vehicle to road surface that ever ran on our modern highways The public resentment or regret, as the case may be, against the destructive effects of automobile traffic should be tempered by the recognition of the fact that it has been the most active instrument in awakening the public to the necessity for abandoning the old slipshod methods of road building, and constructing them according to the best engineering practice

If it were possible to rebuild all our roads of the most approved and highest class of construction, and if the most suitable material were everywhere available, the problem would be greatly simplified, but such uniform excellence is impossible, both because of the cost and of the difficulty of finding the ideal materials within economical hauling distance of the work In a country of such wide extent and such varied geological formation as the United States, the question of the best kind of roads to build in any locality must be determined largely by the local conditions—the climate, particularly as regards the amount and distribution of the rainfall, the nature of the underlying soil its bearing quality, capacity for quick drainage, etc, and above all, the character of the materials available for road building, must all enter into the problem

The French engineers, with their characteristic thoroughness, have long recognized the importance and complexity of the good roads problem, and nearly half a century ago they commenced that careful investigation which is still being carried on by a force of trained experts. The analytical study of the subject, which was set on foot by M Buffet, Engineer of Roads and Bridges, as far back as 1868 has developed into the present municipal laboratory, which has so greatly extended its field of work that to-day it is considered by many to be the finest in existence At the date mentioned, apparatus was installed for testing the resistance of paving materials to wear by friction, which was followed by a machine for testing the resistance to abrasion of the stone used in Macadam roads The laboratory also includes means for artificially producing those conditions and forces of a climatic character which tend to break up and destroy road surfaces

Now here, it seems to us, is a plan which might very well be followed in this country by the founding of a national good roads laboratory, say at Washington, which might co-operate with similar but smaller institutions provided for and controlled by the various State legislatures. The cost of carrying on such institutions would represent but a moderate percentage of the money that is annually thrown away on the construction and so-called repair of highways by the present defective methods.

### RATIONAL STREET LIGHTING

THE proper lighting of a city is not so much a question of the total quantity of light provided as it is of its proper distribution. Because of the fact that America is the birthplace of modern electrical illumination, and the country in which it was first developed on an extensive scale, there is a popular impression that our municipal lighting is the best in the world, yet it is a truth that, because of the unscientific way in which we have distributed our lighting, the resultant illumination, judged by its adaptability to the needs of the user, is far less satisfactory than it might be, and, in its general results, is not as efficient as the lighting of European cities. This question was recently dealt with by Dr Louis Bell in a paper read before the American Society of Municipal Improvements at its annual convention, and the principles which he laid down are at once so obviously sound and so frequently disregarded, that they are well worthy of careful study by the municipal authorities throughout the country

The fundamental criticism against most attempts at street lighting lies, according to the author of the paper, not so much in the illuminants used as in their improper adjustment to the needs of the city The fault particularly noticeable in American cities is the lack of careful discrimination between streets which demand considerable light and those which are perfectly illuminated with a less quantity of light Most schemes of lighting aim at an approximation to uniformity of illumination over the whole area of the city, whereas, its quantity and character should rather be determined by the particular character of the streets in which it is placed The main thoroughfares, in which there is considerable night traffic, should receive an amount of lighting commensurate with their importance, but in streets where traffic is light, and where passers-by are few, it is sufficient to provide enough light to enable the people to get about comfortably So also, a third class of streets, lying more remote and coming under the head of suburban roads, require yet another method of illumination Since the fundamental purpose of lamps in the outlying, little-used streets, is to serve as markers of the way, the using of very large units, widely spaced, is obviously improper, a better way would be to employ small units located at shorter intervals.

The principal streets of American cities, according to Dr Bell, as a rule are poorly lighted, the secondary streets are lighted sometimes better and sometimes worse than they should be, and the third class usually have one lamp in every long block, which is useless, except within a comparatively short radius, for such purposes as finding the number of a house or reading the address in a note book. As to the absolute amount of light required, the principle should be followed that in the principal streets one should everywhere have enough light to read a paper by, which is the standard of illumination adopted in the principal streets of the large cities of England and continental Europe

Much of the faulty street lighting in the United States is chargeable to the method commonly employed for measuring street illumination The usual plan is to measure the light half way between the lamps with the photometer disk held normal to the ray, and, naturally, the tendency of competitors for the lighting contracts is to secure the specified minimum at as low a maximum as possible Indeed, certain types of illuminants have been deliberately specialized for the purpose of giving two-hundredths or three-hundredths of a foot-candle at a distant point. Now, if these illuminants had been designed as they should have been, not to give a special form of illumination, but to give the best efficiency of which they were capable, it would be possible to make them light not only widely distant parts of the street, but the whole street While it is not desirable to attain to uniformity with a low average of light, it is equally undesirable to concentrate the light at certain points separated by long stretches of comparative darkness Summing up, the important points to bear in mind are, first, that streets are lighted for the people to use, second, that the streets should be lighted with reference to the particular use which is going to be made of them, and third, that, speaking generally, all the streets should be more brilliantly lighted than is customary in the United States to-day

### A BATTLESHIP FLEET IN EACH OCEAN.

FOR many years our Navy Department has followed the policy of concentrating an unusually large percentage of the total displacement of our ships in battleships of the first class. Every nation is following the same policy to-day, and has done so since the introduction of the first dreadnought in 1906 Many years before that date, however, the United States had practically ceased to build protected cruisers, and was concentrating its strength in vessels of the armored class, the majority of which were heavily-gunned battleships.

The advantage of this policy is seen in the fact that in a year or two's time it will be possible to maintain two complete battleship fleets, each of four divisions of four ships, one in the Atlantic and the other in the Pacific. Each of these fleets would possess a certain number of dreadnoughts, and would, therefore, be individually much more powerful than the one which made the recent cruise around the world Although the department does not contemplate making such a division of our battleship strength at this time, [illegible] the steady growth of our navy [illegible] position to thus safeguard each [illegible] deemed advisable to do so.

The plan which is now under consideration is to make, within the near future, a complete reorganization of the Atlantic fleet. The details of this organization, which is evidently official, are published in the current issue of the Army and Navy Journal. It is proposed to place five ships in each division instead of four, so that all the ships may dock at their home yards twice a year, and one ship may be in her yard for repairs at any time, without taking from the usual strength of the division. The four divisions will be assigned to the yards at New York Norfolk, Philadelphia and Boston, one division to each yard—a disposition which will enable the division commander to have his force at all times under his eye and immediately within reach. Practically no ship will be out of commission or in reserve, and when the vessels are in the yard for overhauling, they will have as nearly a full complement of men as possible, no battleship crew being allowed to go below 350 men—a force which would be sufficient to maintain the ship in condition to go into service at twenty-four hours' notice. The first division will dock at the New York yard, the second at Norfolk, the third at Boston, the fourth at Philadelphia, and the armored cruiser division at the Portsmouth yard

If the present plans are followed the battleship fleet in the year 1911 will be made up as follows: First Division, flagship "Connecticut," and the five dreadnoughts "Florida," "Utah," "Delaware," "North Dakota," and "Michigan" Second Division, the dreadnought "South Carolina," and the sister ships "Louisiana," "Kansas," "Vermont," and "New Hampshire" of the "Connecticut" class. Third Division, the four sister ships "Georgia," "Nebraska," "New Jersey," and "Virginia," of the "Georgia" class, and the "Ohio." Fourth Division, the "Minnesota" of the "Connecticut" class, the sister ships "Mississippi" and "Idaho" (smaller "Connecticuts"), and the sister ships "Maine" and "Missouri" There will be a fifth division consisting of the four armored cruisers "Tennessee," "Washington," "North Carolina," and "Montana" In the year 1912 we shall have sufficient battleships to provide for a fleet in active service, consisting of twenty-one battleships and a Reserve Fleet of eleven of the older battleships. The first division of the active fleet will consist of six dreadnoughts, the second division, of two dreadnoughts and three "Connecticuts", the third division, of three "Connecticuts" and the two smaller "Connecticuts," "Idaho" and "Mississippi," and the fourth division, of the five vessels of the "Georgia" class. The fifth division (armored cruisers) would consist of the four ships of the "Tennessee" and "North Carolina" class.

Our readers will recognize at once that in the above organization, ships of the same general type have been assembled in the same division. The largest vessels will dock at the New York and Norfolk yards, where the largest drydocks and the best facilities are to be found. The commander-in-chief and the auxiliary vessels of the fleet will make their home at the New York yard since that is the most central point for the purpose. The reserve fleet will be kept at Philadelphia, and the most effective destroyers and torpedo boats will be maintained in commission at New York, Boston, and Norfolk.

By the year 1912, then, the United States navy will contain thirty-one battleships, made up of four divisions, with four ships in each division always ready for sea service and one at the yards for overhauling and refitting, and each division commander will have all the ships of his division within immediate reach throughout the whole of the year. At the same time, should the political situation be such as to render this desirable, as we have noted above, it will be possible to divide this force into two fleets, one for each ocean, each fleet being of considerably greater fighting strength than the one that made the memorable cruise around the world.

---

W. R. Ham finds by direct observation on the primary Roentgen rays that a polarization exists and is independent of the position of the normal to the target. The max. intensity is, within experimental error, in the plane through the target normal to the kathode-ray stream, and the intensity falls off symmetrically on either side of this plane. The interposition of sheets of silver and tin causes an increase in polarization which reaches the same upper limit for both metals. Lead decreases the polarization, but no lower limit was observed. Aluminium, paper, and glass cause very slight changes, if any, in the polarization. All the observed results are [illegible] explained if it be assumed that the primary Roentgen-ray beam consists of a mixture of primary and secondary rays originating in the target, and that the secondary rays are [illegible]

## ENGINEERING.

The fine old cup defender, "Volunteer," which was bought by Capt. Bart last year, has been sold to a firm of wreckers, who will break her up for the value of the lead and fittings. She was the craft that proved so thoroughly the master of the Watson cutter "Thistle" in 1887. "Thistle," by the way, under her present name of "Comet," is still in good shape, and is still being used, we believe, as a training ship in the German navy

The three engineers appointed by the Canadian government to consider the application of the St. Lawrence Power Company for permission to dam the Long Sault Rapids at Cornwall, Ontario, report that the enterprise is worthy of most serious consideration. They urge that, before the government approval is given, there should be a complete agreement between Canada and the United States as to the supervision and control of plants on both the Canadian and New York State banks of the river.

It is officially stated that all the excavation that was contemplated in the original project of the Panama Canal has now been completed The original plans of the canal called for the removal of 103,795,000 cubic yards of material, and a few weeks ago the total excavation done to date under American occupancy had reached that amount. The 71,000,000 cubic yards remaining to be excavated represent the additional work necessitated by the enlargement of the canal, which was decided upon during the Roosevelt administration

The Canadian government is giving consideration to a project for a freight traffic railway to Hudson Bay, surveys for which are now being made. An unusual feature is that the new road would have to be operated to its full capacity for about two months of the year, during the moving of the grain crop, and that for the other ten months there would be scarcely sufficient traffic to warrant operation It is estimated that sixteen trains per day could be handled over the single-track line, and sixty-four million bushels of wheat could be delivered in thirty days' time

The battleship "Indiana" has undergone some tests of the "ship brake" with which she has been equipped This device consists of a pair of steel wings, hinged to the vessel's side and normally held against the ship, which, when a quick stop is to be made, as in the case of impending collision, are released through mechanism controlled from the bridge. They swing open automatically through the forward motion of the ship, and it was found that the vessel could be brought to a stop within the distance of her own length without injurious shock or strain

The "Neptune," the latest of the British dreadnoughts, will have, it is stated, the same length over all, 560 feet, as our own "Wyoming," but her beam will be several feet less than that of the American vessel. She will carry ten 50-caliber 12-inch guns in five turrets, the two turrets amidship being placed diagonally, so as to enable all ten guns to be fired on either broadside Her concentration of fire from her 12-inch guns will be six ahead, eight astern, and ten on the broadside, as compared with the "Wyoming's" fire of four ahead, four astern, and twelve on the broadside

The United States Steel Corporation, which recently made a general increase in wages, has decided to put in force a system of pensions and disability payments for the wives and children of those killed in its employ, and of disability payments for the injured The corporation will also shortly put in force a pension system for superannuated and disabled employes. This movement is to be most highly commended In its humanitarian aspect, it will be a great boon to the employes, and its wisdom as a means of promoting loyalty and checking the growth of anarchistic sentiment is unquestioned.

Construction work will shortly commence on another of those stupendous buildings which are rapidly earning for New York the right to be called a city of towers. The new structure, which is to be built at the northwest corner of Wall and Nassau Streets, on a ground plan measuring 94 by 97 feet, will extend 539 feet above the street level, an elevation which will make it the third tallest office building in the world, the Metropolitan tower being 700 feet high, and the Singer tower 612 feet. The tower will be finished with a pyramidal cap 94 feet in height, which will be utilized for holding the water tanks.

The Great Central Railway of England recently performed the feat of transporting a 77-ton casting upon a 50-ton car. This was done by coupling a flat car on each end of the carrying car, and mounting upon each of the flat cars a massive, trussed, oak girder. The inner ends of these girders extended above the ends of the 50-ton loaded car, to which they were attached by chains. The girders were pivoted at the center of the two flat cars, and their outer ends were loaded with about 9½ tons of dead weight. This arrangement served to transfer 19 tons of the load from the carrying car to the flat cars, thus bringing the actual load [illegible] of the car.

## ELECTRICITY.

At a recent meeting of the Electrical Club of Chicago, it was brought out that there are three thousand storage battery automobiles in Chicago. There are thirty-three storage battery installations in the city with an output of 47,000 kilowatts, while in New York city the total output is 57,000 kilowatts.

An old barge has been equipped with electric welding apparatus at Gothenburg, Sweden, to be used in repairing the boilers of steamers. The equipment consists of a De Laval turbine and two direct-current generators. The current is conducted to the steamer requiring repairs by means of a pair of cables, and work can thus be done within the boilers with power generated on the barge. The barge is also fitted with a workshop where small repairs may be made.

An enterprising newspaper in South America is about to install a wireless telegraph system at its main office. This will be the first wireless newspaper office on the continent. The paper we refer to is La Prensa, of Buenos Ayres. The Argentine Republic is going to celebrate its hundredth anniversary with an exposition this year, which opens on May 25th, and La Prensa expects to keep in "wireless" touch with the exposition grounds.

A French inventor, M Paul Jegou, has devised an electrolytic detector which operates without the use of a battery to affect telephone receivers. The detector consists of a glass cup containing at the bottom a small amount of mercury with some pure tin in solution This serves as one electrode, while the other electrode is of the usual type, namely, a fine Wollaston wire. Dilute sulphuric acid is used for the electrolyte The detector is found to act like a small battery, and yet possesses all of the sensitiveness of the electrolytic detector One of these detectors used at Paris was found to receive signals sent from the Ouessant post on the coast.

Considerable attention has been directed of late to the effect of sunlight on the transmission of Hertzian waves. A writer in Elektrotechnische Zeitschrift, in commenting on this subject, points out that the stronger the sunshine the less the conductivity of ether to the Hertzian waves, so that it is incorrect to speak of a wireless telegraph station as having any definite range, for one which has a large radius of communication in northern latitudes would have a much smaller radius in the tropics This would be particularly noticeable on vessels sailing north and south, and he suggests that it would be desirable to prepare a "radio-topographical" map, giving the relative conductivity of the ether at different latitudes

A comparison of the inclosed arc and the intensified arc for indoor lighting was recently presented before the Minnesota Electrical Association convention It was shown that because of the large carbons used in the inclosed arc, the carbons being half an inch in diameter, the arc is apt to wander along the edge of the electrode, so that instead of giving a uniform distribution of light, the light is greater on one side of the lamp than on the other With the intensified arc lamp, there is no wandering of the arc. The electrodes are much smaller, consisting of two upper electrodes a quarter of an inch in diameter, and a lower one three-eighths of an inch in diameter If the same amount of current is passed through this lamp as through the inclosed arc lamp, the electrodes will be heated to a higher incandescence, thus giving a greater and steadier light.

The Board of Underwriters of Chicago has issued the following requirements for wireless telegraph installations Aerial conductor must be at least No. 8 B and S. gage rubber-covered wire run on petticoat insulators on exterior of building and on knobs, cleats or in molding in interior of building. Porcelain bushings to be used through walls, partitions and floors. Aerial conductor must be permanently and effectively grounded at all times when station is not in operation by a conductor not smaller than No. 4 B. and S. gage rubber-covered copper wire run as nearly in a straight line as possible to a water pipe at a point on the street side of all connections of said water pipe within the premises, or to some other equally satisfactory artificial earth connection, such as an iron rod or pipe driven at least 5 feet into the earth. Ground wire should be protected from mechanical injury by inclosing it in molding at least 7 feet from the ground on exterior of building. The switch employed to join the aerial to the ground connection must be an approved 100-amp, single-pole, double-throw knife switch placed as nearly as possible to where aerial enters and must effectively cut off all apparatus within the building. Aerial conductor may be permanently connected at all times to earth through an approved lightning arrester placed as nearly as possible to the point where the wire enters the building and grounded as specified above. Ground wires for lightning arresters must not be attached to gas or steam pipes within the building, nor be run inside of iron pipes.

## SCIENCE.

In a recent number of the Astronom Nachr., C. Ceraski calls attention to a new variable star or nova, found on a plate taken March 23rd, 1909, at 10h 6m. to 12h. 6m (Moscow mean time) The image was found in a position that was vacant on 24 previous plates, showing stars down to 12.5 magnitude. The star's approximate position is $\alpha = 8h\ 29m\ 26s$, $\delta = +53$ deg 50 min (1900)

G. A. Campbell recently conducted some experiments to investigate the subject of telephone intelligibility In his experiments, usually only detached syllables were employed, so as to give the listener no clue from the context. The syllables easy to interchange are right in about half the cases Thus while it is obvious that the telephone seriously distorts speech waves, nevertheless, even those consonants which nearly resemble each other are not sufficiently distorted to be indistinguishable

A good photometric measurement of the brightness of the nucleus of Halley's comet was obtained on April 21st by Prof Wendell at the Harvard College Observatory The measured magnitude of the nucleus was 6 4 The total brightness of both the nucleus and the surrounding coma was a little above the fifth magnitude. With the approach of the moon toward the region in the sky in which the comet is found there will be very little to repay the early riser In fact, astronomers do not look for any spectacular display while the comet is in the eastern sky

From a study of the radio-activity at the earth's surface, made by G A Cline, it would seem that the soil contributes by far the greater proportion of the penetrating radiation present at the earth's surface at Toronto, and by comparison any that may have its source in the atmosphere or in the sun may be considered to be negligible in amount There are no regular diurnal maxima or minima, but there are changes from day to day which seem connected with concurrent barometric changes The conductivity is greater when the ground is bare and warm than when it is frozen and covered with snow Filtering air through cotton-wool still leaves many suspension particles

A letter has been received from Prof E B Frost, director of the Yerkes Observatory, at Harvard College Observatory, in which Prof Frost records recent observations of Halley's comet. He found the comet more conspicuous than the adjacent star Praesium, and Prof Barnard estimated the nucleus which was not stellar, to be two magnitudes fainter than this star On April 14th the comet was photographed with six minutes exposure No tail was visible with any of the instruments Visual observations of the spectrum were made by Prof Frost and Dr Slocum, and showed a distinct continuous spectrum from the nucleus No bright bands or lines were seen The intensity of the continuous spectrum relative to the emission bands, has greatly changed since the comet was visible in the evening

Some idea of the enormous amount of labor required to extract radio-active substances from their ores may be gained when it is considered that to obtain two milligrammes of substance containing 0 1 milligramme of polonium, it was necessary for Madame Curie and A Debierne to treat several tons of uranium Fairly pure helium was isolated from the gases given off by a solution of polonium under a high vacuum in a quartz tube, due to the action of the alpha rays emitted by this element. The life of radium is about 5,300 times that of polonium (which is reduced to one-half in 140 days) The spectrum is being studied with a view to ascertaining if an inactive element is derived from it, polonium according to theory, being the last radio-active term in the series of derivatives from radium The atomic weight was estimated to be about 200

A new preparation has appeared which cleans and polishes silver, silver plate, nickel and other white metals, and which is said to produce a plating on pure silver and any metal except gold by mere contact of the preparation with the metal In view of the publicity given lately in British scientific journals to a similar preparation invented by Rosenberger it is interesting to note that the American article has been known in the United States for several years although offered more prominently only since 1908 Rosenberger's preparation requires a different modification for each metal The American preparation is a white, creamy liquid, perfectly stable and unaffected by light, and is claimed to be perfectly free from mercury, acids and other injurious ingredients. So far as we are able to determine, its plating action seems to be due to the affinity which the metal to be plated exerts upon the molecules of silver in the solution, so that the resultant plating is identical with that produced by ordinary dynamic electroplating No electric current is necessary to produce the plating nor is an addition or admixture of any other substance required.

Demonstration train at a way station in California.

In response to an urgent request from leading dairy interests in Southern California, Prof Leroy Anderson, head of the dairy department of the California College of Agriculture, has just made an examination of the milk conditions in that part of the State.

Prof Anderson says that in consultation with the dairymen, it was decided to inaugurate a general policy of education upon the subject In his opinion, the reform of many conditions now undesirable in the methods of producing milk, can better be reached through the commercial aspect of the business and through the education of the producer and the consumer than through drastic and radical legislation

He says that he finds the conditions under which milk is produced about Los Angeles are not materially different from conditions in other populous centers, except that nature is possibly kinder in granting more sunshine and less rain and a more porous soil, all of which tend toward an easier cleanliness

What advice he has to offer, therefore, is applicable to all parts of California. He hopes especially that the man who is producing and selling directly to consumers in the smaller towns and cities, whether he has one cow or more, may receive an incentive to have better cows and keep them in a clean and a healthy condition

In cities like Los Angeles and San Francisco, he says, where large wholesalers act as distributing agencies between the producer and the consumer and pasteurize all the milk, some of the dangers that might result from disease of the cow and uncleanliness are obviated

"It does not have a pretty sound," continues the professor, "to say that lack of care on the part of the producers is partly the reason for the expensive pasteurization which the wholesalers now give to milk."

"Pasteurization, however, is one of the advance steps toward a healthier race, and some day this process will give way to such clean methods of producing milk that it will not be necessary That is the goal toward which we are all striving '

"It costs money to produce clean milk, which cost must be met by a higher selling price or by more profitable cows, or both The cow is especially in our mind just now, and we call the reader's attention to records taken from different sources to show by actual figures how cows vary in returns to their owners from similar outlay for food and care"

Prof Anderson then refers to the subject of proper stables and corrals for dairy cows and says

"The great thing to be desired in either, is that there should be easy means of keeping clean and then keep them clean. This is the chief reason for using concrete in stable floors It does not decay and then cause foul odors, and it can be hosed down with water and swept in a few moments, so that no dirt remains. Some dairymen object to cows standing on concrete, but in California, where the cows are in only for feeding and milking, they suffer no injury

"Occasionally a very good stable is constructed where the cattle stand, which portion is made of plank This works well from a sanitary point, if the planks are water-tight or are underlaid with a water-tight substance so that the soil under the planks cannot become saturated

"A milking stable is absolutely essential to the production of clean milk Milking in the corral is an abomination, either in winter or in summer In winter, during the rainy season, it is not uncommon to see both cow and milker wading nearly to the knees in mud, when of necessity the milk must become the depository for some of the mud.

"In summer, when the corral dust may be from one to four inches deep, the condition is even worse The dust is raised with any slight breeze or with every movement of man or beast, and even more dirt finds its way into the milk than during the time of rain and mud Thus the cows must be provided with some stable which is dry and clean, and where they can be held for milking

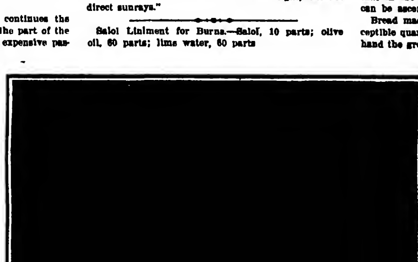
"The stable needs not be expensive On the contrary, it may be very simple, and the less lumber in it the better so long as the frame is sufficiently strong It should permit the entrance of an abundance of direct sunlight and have enough openings to give constant ventilation Large louvers in the roof are excellent for ventilation and also admit light, but not direct sunrays."

Salol Liniment for Burns.—Salol, 10 parts; olive oil, 60 parts; lime water, 60 parts

**Bread Under the Microscope.**

Bread, like milk, is one of the most general articles of food, and as such is subjected to the most frequent adulteration, and unfortunately it happens that such a fraud cannot always be detected with ease. The experts who have given especial attention to this kind of adulteration agree in the statement that under the influence of the preparation of bread the grains of flour undergo certain changes in their outer appearance that render them much less distinguishable. In a most praiseworthy article recently published in Les Annales de la Chimie Analytique, Eugène Collin recounts the results of his tireless examination of pure bread and adulterated bread. In the course of his laudable endeavor, it seems, he found himself able to determine with passable exactness the quantity of pure flour in baked bread, whether the bread subjected to microscopical examination was old and hard or fresh His procedure was to soften a crumb of bread with as little water as possible and knead it persistently with forefinger and thumb over a fine sieve resting on a vessel that should receive the dripping water The mass is treated in this manner until the water ceases to look darkened A powdery mass then remains on the sieve, which is deposited on the crystal of a watch, combined with a trifle of glycerine, and is then set aside for further examination Besides, to the water in the vessel is given an opportunity to clear itself, and it is then decanted so carefully that the sediment is not disturbed The result of such treatment is that from the deposit on the sieve and that in the vessel the true composition of the bread can be ascertained.

Bread made from pure flour leaves only an imperceptible quantity of starch on the sieve On the other hand the greater part of the gluten is found on it and forms a net of irregular meshes and shows some resemblance to vegetable tissue In consequence of the ease with which its presence in the bread is ascertained, the gluten is especially important for microscopical examination. In the same deposit the microscope showed numerous particles of starch which during the preparation of the bread changed their ordinary form or were forced to explosion. Still there is a rather considerable number of them that have escaped this influence and are easily recognized from their size, color, form, and the presence of the navel. These statements regard wheat bread only. The result when rye bread passes under the same procedure is that the deposit on the sieve consists of gluten only, and therefore proportions in a mixture of both kinds of flour can be ascertained with a large degree of exactness under the microscope. Particularly, however, is this done through a test of the precipitate of flour, since the grains of starch of wheat and of rye are distinguished from one another by the [illegible]



Lecture in agricultural and horticultural [illegible]

Dairy exhibit, agricultural demonstration train.

Cereal exhibit, agricultural demonstration train.

A RAILWAY SCHOOL FOR FARMERS.

placenta. The most resemblance to these is shown by the grains of barley, the addition of which is ascertained with a satisfactory degree of certainty from the precipitate on the sieve A quite customary adulteration of bread is effected with rice flour, which always fails to escape the scrutiny of the microscope when this is invoked, for the grains of starch of rice are always left in great number on the sieve and are more easily recognized because during the preparation of bread they suffer less change. This result of M. Collin's investigation is extraordinarily important, for the addition of rice flour to wheat flour or to rye flour has begun to be a veritable torment Besides, certain kinds of corn meal have been misused in the same way, though easily detected by the microscope

# A REAPER BOAT

## BY THE PARIS CORRESPONDENT OF THE SCIENTIFIC AMERICAN

A French constructor, A Amiot, has brought out a type of boat combined with a set of cutting blades, which is designed for use in cutting off aquatic growths in ponds or artificial lakes, mill races and various water courses Such operations are often necessary where the bottom of a pond or water course becomes obstructed by the thick growth of aquatic plants, but where it is required to be carried out by hand labor it becomes a difficult and also an expensive matter, especially where a large area has to be dealt with. M Amiot's device overcomes the difficulty by using an internal combustion motor mounted on a boat, and the motor serves to drive a set of cutting blades, which are designed somewhat after the fashion of reaper blades and adapted in their form so as to carry out the cutting of the plants under water in the best manner The boat is rather narrow, and flat bottomed, being much narrowed at the front and the rear In the front is carried a paddle wheel, which is run by a gasoline motor, which drives the boat at a slow speed Its total length is about 20 feet.

The cutting bars are mounted at the lower end of a vertical frame, which is held at the rear end of the boat, and these extend transversely across the bottom of the frame so as to lie at a point near the bottom of the water course or pond and to cut off the plants as the boat advances. Such bars are made in different lengths and also at different curvatures so as to be adapted for flat bottoms or for beds of streams of different forms and sizes. The bars are usually from 6 to 12 feet in length, and are designed to cut off a considerable area at a time. This gives the present system a great advantage in being able to cover a large surface within a short time and at a comparatively small cost. As will be observed in our engraving, the frame, which is made up of two vertical angle irons braced in the proper way, is suspended on the end of the boat, and [illegible] being swung upon the end of the lever, which is observed at the upper part, and this lever is pivoted in an upright. By means of the counterweight at the end of the lever, the entire frame can be raised and lowered, and this gives the adjustment of the cutting bars at any desired height in a convenient way The gasoline motor is placed at the other end of the boat, and there is a belt transmission running to the rear end, which operates the pulley placed in the upper part of the cutting bar frame This does not interfere with the raising or lowering of the frame, as will be noticed, seeing that the belting and pulleys can work at different angles. On the shaft of the pulley is a crank which drives a rod, and this last passes down along the frame to the lower part, where it connects with a rack and pinion movement By means of the alternate up and down movement of the rod, and the rack and pinion at the lower part the cutting blades are given the to and fro movement in the same way as is seen in the usual blades, and in this way a wide swath is cut under water and at any desired height above the bottom The paddle wheel is carried on a frame which is adjustable by means of bolts, so as to give the paddles any desired immersion, and the gasoline motor drives the wheel by gearing and chain device, using two separate countershafts for this purpose so as to give the needed speed reduction The gasoline motor is operated at the standard speed of 500 revolutions per minute When it is required to take the boat into shallow water or otherwise to pass over rocks or other obstacles, the cutting frame can be lifted entirely out of the water In this case the cutting bars are folded up along each side of the frame so as to occupy but little space In usual practice the cutting is carried out at the rate of 1½ miles an hour, and the cost of operating is estimated at $0 35 per mile, comprising gasoline, oil, labor, together with depreciation and maintenance For cutting one acre area, the cost is figured at $2 70

The Amiot system is meeting with great success in Europe, and it is now in use on the artificial lakes of the domain of the Institute of France, at Chantilly, and also on the domain of Lacken, belonging to the King of Belgium It is also used on a number of canals and rivers in France

The upper view shows reaper boat in operation. The lower picture is a plan view showing transmission gearing.

A REAPER BOAT.

According to the Electrical Review and Western Electrician, the Park Building at Pittsburg, Pa., which is 15 stories high and contains 400 offices, was recently lighted by carbon filament lamps and had its interior decorations painted a deep sea green color It is now lighted by tungsten lamps, and has its interior painted a light buff color On replacing 3,910 carbon lamps (56-watt) by 780 100-watt and 200 25 watt tungsten lamps, and 21,840 watts in 16 and 32 candle-power carbon lamps in the corridors and lifts by 3,400 watts in 40-watt and other tungsten lamps, 149 4 kilowatts is saved.

## THE ELEVATOR INSTALLATION OF THE METROPOLITAN LIFE TOWER.

BY HERBERT T. WADE.

In the newly-completed Metropolitan Life Insurance tower is to be found an example of an installation which serves the purpose of lifting cars to an altitude greater than that attained in any building yet constructed. Judged independently of its height, the installation is a model of modern elevator engineering. Furthermore, it is significant of the successful development of a comparatively recent type of elevator machine which has been tested in actual use and found to answer the requirements of service as well as the requirements of mere height. Great as the lift is the designers claim that it is possible to go even higher and that elevators can be installed in any skyscraper which the ambitious architect may yet essay. As a result of this engineering achievement there is no difficulty in renting offices far above the city's noise and dust. No more time is consumed in reaching the 44th story of the Metropolitan tower than the 12th floor of older buildings.

For the Metropolitan Life tower, the type of elevator selected was the Otis traction overhead machine, in which the motor and driving sheaves are situated directly above the hatchway. High up in the apex of this white marble campanile are to be found powerful electric motors, whose installation at this elevation taxed the ingenuity of the architect and engineer. They are without doubt the highest motors working in any building.

The problem of high rise in a tower building is one that can be solved by but few types of elevators. A height of 400 feet marks the limits of the plunger and other hydraulic machines. In many forms of electrical elevators the weight of heavy moving cables or other parts, and the exact regulation of the car or load, are difficult if not impossible of attainment when certain heights are exceeded. In the Otis system illustrated we have a simple machine that has been found to work with ease, safety, and reliability. A motor is mounted at the top of a shaft or hoistway. The armature shaft carries between its two bearings a driving sheave around which the six cables suspending the car are passed. One end of the cables extends to the car, the other to the counterweight, which moves up and down in guide rails at the side of the shaft, and is equivalent to the weight of the car and its average load. Directly below the driving sheave is fitted an idler sheave, around which the supporting cables are laid, so that it passes again around the driving sheave with which it is in contact for two half-turns. When the current flows through the motor, the armature rotates and moves the car up or down as desired. When the current is cut off powerful automatic shoe brakes are applied to hold the driving sheave. A compensating cable in older installations a chain is connected with the bottom of the car, extends to the bottom of the shaft, passes around sheaves or pulleys, and then extends to the counterweight. Its object is to compensate for the weight of the supporting cables, whether the car is at the top or the bottom of the shaft. In other words, the system is very nearly in equilibrium, and the function of the motor is merely to move it with such additional load as is supplied by the passengers in the cars. When the Metropolitan installation was considered by a board of elevator engineers it was realized that this system was the only one that would meet the conditions demanded in an office building of extreme height. The thorough tests which the machines have received since their completion has justified the engineers in their selection.

The Tower installation, which is quite independent of the elevator systems serving other parts of the huge Metropolitan Building consists of six express elevators, which make no stops between the street and the 10th floor. The cars are arranged in the center of the tower in two banks or rows of three each, five of the six running from the 1st to the 41st floor, or a rise of 524 feet 11½ inches. The middle car on the east bank runs from the basement to the 41st floor, while the middle car in the west bank runs from the basement to the highest landing in the tower on the 44th floor, a distance of 586 feet 5¼ inches. With a live load of 2,500 pounds, or about 16 passengers, the cars can make a speed of 600 feet per minute without stops, which is the maximum permitted by the present New York Building Department regulations. Thus the journey to the top floor consumes but a few seconds under a minute which is recognized as about the limit demanded by office building renting conditions. The actual consumption of time by the passenger does not place the tower building at any disadvantage over lower buildings, where slower speeds and frequent stops may require the same expenditure of time. In this connection it may be remarked that the traction machine illustrated can accelerate from a stop to full speed in from two to three seconds smoothly and evenly, so that the passenger experiences no unpleasant sensation.

Each elevator is expected to travel up and down daily a total distance of 25 to 30 miles. [illegible] of the engineer naturally centers in the [illegible] have been installed at the top of the [illegible] most extraordinary conditions; for as the view of the tower shows, the tapering top affords little space for heavy machinery.

Elevator installation was not a final feature of the construction of the tower, but an ever-present condition. As fast as the structural workers completed the framework, the rails for the cars were set in place, and a temporary elevator was rigged to send up the materials of construction. As the material for the five machines for the elevators running to the 41st floor could be carried up by the high-rise elevator, their erection was not so difficult a matter. When it became necessary to raise the machine for elevator No. 2 up to the 45th story, a serious problem was presented. Eventually, the task was accomplished, and the huge castings and armature were sent up to a point where they could be set in place by an ordinary tackle. These machines weigh 21,000 pounds each in the case of four, and 23,000 pounds each for two elevators where devices are employed to enable extra heavy loads, such as safes, to be raised. The magnet controllers weigh 2,000 and 2,300 pounds respectively for the two classes of machines. It is here that the operation of the switches governing the motors centers, which switches are under the control of the car operator.

The motors are rated at 40 horse-power and use 115 volts direct current. They run at a speed of from 35 to 58 revolutions per minute, and the peripheral velocity of the driving sheave on the armature shaft gives the speed of the car. The limited space in a high tower presents problems quite different from those of a large building, such as that of the Hudson Terminal, where the traction machines can be arranged in orderly rank. In the tower one machine may have to be placed above the other, or at an angle perhaps, while the controllers and other auxiliaries must be fitted in wherever a place offers. Consequently, the machinery room of the tower has a bewildering appearance. Every inch of space is utilized. Despite crowded quarters, there is the utmost order.

Around the driving sheaves pass the lifting and counterweight cables, six in number for each machine. They are ⅝ of an inch in diameter, and each cable has a breaking strength of 30,000 pounds. The length of the several cables for the various cars varies from 575 to 626 feet for the high-rise car. Another important cable is that passing through the car to the centrifugal speed governor at the top of the hatchway. These are ½-inch cables, and they vary in length from 1 144 to 1,274 feet. Their function is to transmit the motion of the car to the centrifugal governor, which in case of excess speed, not only cuts off the power, but causes the safety device of the car to come into play and lock it firmly to the rails. The cars, which vary from 5 feet 4 inches by 6 feet 4 inches to 5 feet 4 inches by 8 feet, weigh about 4,000 to 4,500 pounds each. The counterweight is slightly heavier than the empty car, so that the car is assumed to carry an average load.

In the more recent Otis traction elevators, the clanking chain used to compensate the weight of hoisting and counterweight cables has been supplanted by a special flat wire rope, which is 3¾ inches wide and ¼ of an inch thick, one end being attached to the bottom of the car and the other to the bottom of the counterweight. This cable passes over flat flanged sheaves, arranged in a channel-iron frame at the bottom of the shaft, which frame is carried in such a way that the sheaves are free to move up and down as the hoisting ropes stretch or contract. Two of these compensating cables are attached to each elevator, their length varying from 578 to 630 feet.

Safety no less than speed is insured for these express elevators. Thus the speed governor already referred to serves to actuate a wedge-clamp device on the car, and to limit the speed electrically to 700 feet per minute. If a speed of 800 feet per minute is reached, the wedge-clamp safety device works at once, and the car is clamped to the rails. Furthermore, each car has an emergency brake which enables the operator to shut off the power and clamp the car to the rails independently of the speed governor. At the top of the shaft, safety retarding devices check the speed of either car or counterweight in case the ordinary limit of travel is exceeded.

Both cars and counterweights land on patented oil buffers at the bottom of the shaft, which buffers are arranged so as to stop the cars when running at full speed, that is, under 800 feet per minute, and these have been found to work by actual test most effectively and satisfactorily.

---

The Suez Canal is quite a different affair to-day from what it was when it was opened in 1869. Mr. Vice-Consul Dunlop gives some interesting details of how the canal has been developed to make the [illegible] [illegible] From 1896 to 1904, owing to the increased dimensions of ships, larger gares were begun, some 10 in number, at intervals of three miles, each gare having an effectual length of 820 yards, with approaches of 328 yards at either end. At each gare the bottom width of the canal is 50 yards, the width at the water level being over 100 yards, while the depth of the gare itself is 31 feet. At the same time the depth of the channel was increased, so that on January 1st, 1902, a draft of 26 feet 3 inches was allowed instead of 25 feet 7 inches. On January 1st, 1906, the draft for ships was again increased to 27 feet, and on January 1st, 1908, to 28 feet. The work of deepening the channel is steadily proceeding, with the intention of arriving at a uniform depth throughout.

### An Ingenious Way of Examining the Contents of the Duodenum.

The lay mind is apt to consider the advances made in surgery in the last decade of more importance than those in modern medicinal practice. That this popular impression is erroneous is proved by the many devices which have of late years been put to successful tests to enable a physician to examine with the greatest accuracy the workings of inner organs and to restore them to their normal condition without resorting to the surgeon's knife. Notable forward strides in this direction have been made in the study of the digestive organs of the human body, such as examination of the stomach and its contents by the use of a bucket firmly held at the end of a fine cable and let down into the stomach, to fill and be hauled up again for examination by chemical reaction tests, to determine whether the stomach digests normally or abnormally, and thus to enable the physician to diagnose correctly the defects or diseases of the digestive organ.

From the New York Medical Journal we learn that Dr. Max Einhorn, professor of medicine at the New York Post-Graduate Medical School, has succeeded in obtaining samples of the chyme contained in the duodenum by the use of a very simple apparatus called the "digestive juice aspirator," a portion of which instrument is introduced into the duodenum by way of the esophagus and stomach without the slightest discomfort to the patient.

It is well known that primary digestion takes place in the stomach, but the most important digestive action takes place in the duodenum that is, the part into which the stomach discharges by way of the pylorus, and which also receives the very important secretions from the liver (bile) and the pancreas.

For the purpose mentioned, Dr. Einhorn uses a thin flexible tube terminating in a small metallic perforated capsule, which is swallowed by the patient and passes into the stomach, dragging the flexible tube along in its descent, the tube being sufficiently long to extend a distance out of the patient's mouth.

The capsule in the stomach is acted on by the movement of the stomach wall, as in the case of food. In the course of about an hour it passes by way of the pylorus into the duodenum, and even as far down as the beginning of the small intestine. The outer end of the tube is then connected with a small hand suction pump, the piston of which is gradually withdrawn, so that the duodenal contents are drawn into the perforated capsule and up through the tube into the glass barrel of the pump, which latter is now disconnected from the tube and its contents emptied into a vial for examination. The tube and the capsule attached thereto are then withdrawn.

The immense importance of being able to obtain the chyme directly from the duodenum, especially the lower part thereof, is apparent, as the physician by the subsequent tests made of the chyme obtained, can diagnose accurately and readily determine the proper or improper functioning of the duodenum. The same instrument can, of course, also be used in the stomach, to obtain samples of gastric secretions, during the entire period of stomach digestion, from beginning to end.

The successful use of the simple device described has led Dr. Einhorn to its reverse use, that is, introducing food or medicine directly into the duodenum without first passing it into the stomach, in the ordinary way of swallowing the food or medicine. In this case, the food or medicine in liquid form is filled into the barrel of the pump and after the introduction of the perforated capsule into the duodenum as above described, the pump is attached to the outer end of the tube, and the pump is actuated [illegible] force the food or medicine through the tube and [illegible] forated capsule [illegible]

SCALE IN MILLIONS OF MILES.

Paste this sheet on a piece of 10-ply cardboard. Cut out the three diagrams along the dotted lines. Slot the planes of both the comet's and earth's orbits along the dotted lines running from the sun to the orbits. Insert the planes into each other, keeping the earth's orbit below that of the comet on the right, but above it on the left. The general effect is shown in the photograph. To hold the planes at an angle of approximately 18°, paste two small muslin hinges in the angle between them, one on each side of the sun, keeping the slots in line. Bend the flaps of the triangular angle support along the lines indicated, and paste the support as a wedge between the plane of the earth's orbit above and the comet's orbit below

HOW TO MAKE A MODEL OF THE ORBIT OF HALLEY'S COMET, SHOWING ITS RELATIVE POSITION TO THE EARTH'S ORBIT

## Correspondence

### WEIGHT DISPOSITION IN AEROPLANES

To the Editor of the SCIENTIFIC AMERICAN

I was much interested to read the letter of C E. McCluer of Norfolk, Va. in your issue of April 9th concerning monoplanes and the disposition of weight below the level of the supporting planes.

In a letter I wrote to the Wright Brothers at the time of the unfortunate accident in which a valued officer of the United States army lost his life, I advocated the very principle set forth by Mr McCluer and confidently believe still that the adoption of that method will preclude the possibility of the recurrence of such accidents.

In the letter referred to are sketches illustrating the idea and showing the same in comparison with a bird in the act of flight. The whole thing was submitted without any mercenary motive and was simply for the reason already stated.

As a mere student of aviation I submit the foregoing in the hope that you will publish the same as it may lead to experimentation. ROBERT W MATTHEWS

Lock Haven, Pa.

### WEIGHT DISPOSITION IN AEROPLANES.

To the Editor of the SCIENTIFIC AMERICAN

Mr McCluer's letter in the issue of April 9th exemplifies an error only too common among people who take an interest in aeroplanes Placing the center of gravity low in an aeroplane introduces many objectionable features which more than outweigh its advantages. Far from having a stabilizing effect the low center of gravity makes the machine more unstable than ever and calls for great skill on the part of the aviator to maintain an upright position

This is due to the pendulum effect of the suspended weight. When the propeller attempts to accelerate the machine by increasing its forward thrust it is resisted by the inertia due to the machine's weight and if the center of gravity is below the center of the propeller the machine will tip forward

Likewise on a turn the suspended weight tends to swing out in a larger circle than center of the supporting surface where the resistance is concentrated and so tends to depress the inner wing just the contrary of what Mr McCluer assumes would take place This disturbing tendency is in addition to the depression of the inner wing due to its slower speed

Mr McCluer's analogies to natural forms have much that is good in them and like him I favor the monoplane but I believe that soaring birds will be found on closer observation to keep their weight well up on their wings The only safe principle for an aeroplane is to have the centers of gravity thrust and support as nearly as possible coincident

New York G H GODLEY

### THE "KINKS" IN THE NEGRO'S HAIR

To the Editor of the SCIENTIFIC AMERICAN

The texture of the hair is one of the physical variations differentiating the negro from the Anglo-Saxon Celt or Teutonic races But what causes the kink in the hair of the negro? For centuries and centuries the ancestors of the United States negro have lived in the dense forest and heat of the torrid zones of Africa the atmosphere of which has been enrcharged with sodium calcium magnesium sulphureted hydrogen ammonia iron and other chemical substances Besides these and other known metals the atmosphere has in it various gases which it holds in suspension In the presence of these atmospheric solid and gaseous substances coupled with a constant very "humid condition" of the atmosphere we have the unprotected scalp of the indigenous native with the powerful actinic rays and heat of the tropical sun acting directly upon the head of the Homo Africanus both as an irritant and a trauma This excites a condition known to the pathologist as an inflammation With this condition of inflammation of the skin of the head there follows a congestion and proliferation of the blood vessels of the skin of the scalp with the following result The sudoriferous and sebaceous glands together with their excretory ducts become hypertrophied This makes the entire dermis and epidermis thickened and indurated as the glands of the skin pour their contents out upon the surface of the skin to go through the process known to chemists as oxidation, which produces heat According to the well known principle cold contracts but heat expands, there occurs an alternate contraction and dilatation of the longitudinal and transverse bands of connective tissue and the thin muscle fibers that connect the papilla in which the shaft of the hair is growing This alternate contraction and dilatation of the muscle [illegible] acts as a sort of a "guy-rope," pulling the [illegible] and shaft first in one direction and then [illegible], with the following result The hair as it grows from the root to the epidermis, becomes [illegible] The shaft of the hair, as it [illegible] [illegible]

The heat generated by action of the integuments of the skin in the presence of the atmosphere tends to harden the outer sheath of the hair and gives to it its permanent character

In the temperate zone of the United States where the humidity of the atmosphere is not so dense with our abundance of sunlight where the atmosphere is not so heavily impregnated with metallic corpuscles and gaseous substances and where the Afro-American's head and scalp are protected by the ordinary head gear removed also from beneath the direct rays of the torrid tropical sun the etiological factors which have been operating for ages and ages to make the Afro-American's hair *encowtic* will in time make his hair enthycomic. The modern science of anthropology no longer teaches that Homo Europeaus is of an "Indo-European origin but Sergi makes the affirmation that Homo Caucasicus is of a Mediterranean origin Ripley (see Races of Europe p 175) The Mediterranean population are an offshoot and development from the African negro (See Darwin's Descent of Man, p 171) The probable and acceptable hypothesis is stated by Arthur M Marshall in his biological lectures 1894 p 24 who says The white races of Europe had their geographical genesis in Africa and spread thence in paleolithic and neolithic times over the whole of Europe The white races of Europe and America are therefore of a negro origin and the same causes and elements of nature that have depigmentized the skin and straightened the hair of Homo Caucasicus will in time produce the same results in the Afro-American's skin and its appendages J M BODDY

St. Paul, Minn

### HALLEY'S COMET—A MODEL OF ITS ORBIT.

BY JAMES E LYNCH GEORGETOWN COLLEGE

For the large number of people now interested in the famous Halley's comet who have found difficulty in obtaining an intelligent idea of its motion in space its apparent motion in the sky and the times of its visibility a cardboard relief model like that of which a photograph is herewith reproduced will be of great assistance And even those who already understand the phenomena from the study of plane diagrams may obtain a much clearer idea of them from the model because it is much more concrete and represents the sun and the orbits of the comet and the earth as they really exist in space and not as they are often shown by being projected on the same plane

In order that the readers of the SCIENTIFIC AMERICAN may easily construct such a model for themselves patterns or diagrams are printed on the accompanying loose-leaf supplement which when pasted on card board cut out and properly fitted together will make an excellent model

After telling how to construct the model some description will be given explaining how the astronomical phenomena may be studied from it

Having first pasted the loose-leaf on a sheet of card board about 10-ply cut out the three diagrams along the dotted lines Also cut a narrow slot through the planes of both the comet's and earth's orbits at the places marked Then insert the planes into each other as far as the slots will allow keeping the earth's orbit below that of the comet on the right but above it on the left.

If the two planes are correctly fitted together they will now produce the general effect shown in the photograph But besides having the model rigid the two planes must be given the necessary inclination to each other of approximately 18 degrees

Fasten the two planes together by pasting two small muslin hinges in the angle between them one on each side of the sun keeping the slots in line Then bending over the flaps of the triangle along the two lines marked on it paste it as a wedge between the plane of the earth's orbit above and the comet's below This completes the model

The reader will observe that the comet's position is indicated at intervals of ten days before and after perihelion as it travels in its orbit in the direction of the arrows The earth's position as it yearly moves about the sun in the opposite direction is also shown for the same days The printed side of the model faces north

Examining the comet's path in space we see that it cuts through the plane of the ecliptic at the ascending node symbol ☊ in January On April 19th it was at perihelion On May 18th 19th it cuts through the plane of the ecliptic at the descending node

During the early part of the year the comet and the earth moved on roughly parallel lines Hence the comet grew brighter only by a change in its intrinsic brilliancy Now however the orbits are rounding in toward each other and the comet will be more conspicuous because it is approaching the earth

This tail is always directed away from the sun Hence in March it was much foreshortened for us Now it is becoming more nearly perpendicular to the line of sight, and will soon be seen more in its full length

The time of visibility of the comet will depend on whether it is to the left or right of the sun as seen from the earth To transfer correctly to the sky left and right on the model we should imagine the sun on the meridian at noon with the comet to the left or right. Taking the way that common observation shows the sun to move across the sky from east to west on account of the earth's daily rotation it is easy to see that any body that is to the left of the sun at noon will rise and set later than the sun and anything to the right at noon will rise and set earlier than the sun

Hence before March 25th the comet being to the left of the sun rose in daylight but set after the sun and was visible in the evening At present it is to the right of the sun and rises before it in the morning increasing its distance until May 8th when it reaches its greatest western elongation It then approaches the sun and comes into inferior conjunction on May 18th 19th

As the three celestial bodies are also in the same plane on this date the circumstance makes it possible for us to go through the comet's tail if it is long enough to reach us What we shall see on that night it is not the purpose of the present article to consider but it may be said that as the moon is then approaching full a fact which has been somewhat overlooked we may not see anything at all

The comet and the earth are fourteen million miles distant May 18th 19th but their closest approach occurs a day later when they are thirteen million miles apart The closest approach of the orbits is at a point a little below to the left where the comet's orbit is six and one half million miles below the earth's On diagrams where both orbits are projected on one plane they apparently intersect at this point Hence some people have imagined a possible collision here but the orbits never intersect as the model shows

On and after May 20th as the comet is to the left of the sun in the model it will again be visible in the western sky being seen as soon as it is dark enough and setting about two hours after sunset which time will gradually increase to four hours by the end of May But as the two bodies are then receding in almost opposite directions and the tail is turning more and more away from us the glory of Halley's comet will soon be lost to us for three-quarters of a century

### The Current Supplement

The new 60 ft reflecting telescope of the Mount Wilson Solar Observatory has been in operation for about one year A description of this wonderful instrument and the work which it does is presented in the current SUPPLEMENT No 1 91 by F A Ellerman. Sven Hedin's big Trans Himalaya is reviewed Halley was not only the first to predict the return of a comet but also to devise a method of determining the age of the ocean from chemical denudation George F Becker comments on his work The ancient decimal bead frame is still in actual use side by side with the very latest adding and listing machines This ancient bead frame the Chinese abacus and its Japanese twin brother are described by Mr Daniel Arthur Dr Jean Charcot presents the results of his Antarctic expedition Henry A Wise Wood contributes an excellent paper on Modern Stereotyping and the Mechanics of the Newspaper Substitutes for Rubber is the title of an article which must undoubtedly attract attention because of the present rubber boom Under the title Mechanical Oddities some curious inventions are described The design of aeroplane motors is discussed A Metin suggests an improvement in aeroplanes A box with a secret opening is described and illustrated

### Mercury Arc Patents Granted

After six years contest Mr Peter Cooper Hewitt has been awarded patents for his mercury vapor electric lamp The patents have been in interference almost since the date when they were first applied for in 1901 Mr Hewitt's chief opponent was the General Electric Company

In accordance with the recent decision affecting the classification of articles under the Tariff Act of 1909 the United States Treasury Department has instructed customs officers to admit free of duty all miners safety lamps whether electric or designed for using oils or other illuminating materials with or without glass chimneys and whether imported as an entirety or in separate parts together with any apparatus for locking or unlocking such safety lamps for testing or detecting flaws in these lamps or for cleaning them of dust particles etc together with all mirrors rescue appliances and parts thereof such as helmets special tubing of valves special oxygen cylinders refilling oxygen pumps and all other essential parts of the complete outfit, whether imported as entireties or in separate parts.

# THE MOTOR-BOAT RACES AT MONACO

BY THE PARIS CORRESPONDENT OF THE SCIENTIFIC AMERICAN

The motor boat races at Monaco and Monte Carlo this year were noteworthy on account of the extremely high speed which was attained according to the cable dispatches There were a score or more of boats in the races which were favored with excellent weather that made possible the attainment of great speed especially in the long-distance events

Three of the contestants making a turn in the "Championship of the Sea" race

Stern of the "Ursula," showing rudder and twin screws.

The first long distance race for the Championship of the Sea was held on Sunday April 10th Count de Pourtales Cocorico readily won this 200-kilometer (124 mile) race in 4 hours 22 minutes 45 2 5 seconds at a speed of 28 31 miles per hour Out of the 26 competitors in this long distance race for cruisers the Tek Mora Calypso Gregoire VIII and Spagal Ilnail finished in the order given

The race was an exciting one as several of the boats were quite evenly matched The Brasier Despujols hydroplane which was one of the novel craft that raced this year did very well and showed good speed in proportion to its horse-power In the second great international race for the Coupe des Nations which took place on April 12th this boat was second finishing but 7 minutes and 47 seconds behind the Ursula which completed the 100 kilometers (62 1 miles) in 1 hour 26 minutes 59 2 5 seconds The Brasier Despujols averaged 39 1 miles an hour against 42 88 miles an hour of the Ursula She was fitted with a Brasier 4-cylinder engine of 100 horse-power while the Ursula had two 12-cylinder motors totaling 800 horse-power One of our photographs shows the twin screws of the Ursula. Her engines are arranged side by side one on each side of the hull Another photograph shows the Ursula at full speed while a third picture shows the Brasier Despujols The difference in the amount of spray thrown by these two boats is interesting the former cuts through the water with very little disturbance while the latter skims over it with a good deal of splashing The great regularity with which the Ursula speeded around the course for nearly an hour and a half astonished many of the spectators, and was an excellent testimonial to the design and construction of the Wolseley-Siddeley motors that drove her She was piloted by her owner who steered her with great steadiness. He took the turns without slowing down and at each turn the boat would tip dangerously The Ursula showed herself to be one of the fastest motor boats that have ever been built but in the mile and kilometer speed trials she did not make anything like the time that she is reported to have accomplished in the long distance races In fact the hydroplane beat her in the speed trials owing to its ability to get under way quicker The times of the mile from a standing start and of the flying kilometer trials by the Brasier Despujols and the Ursula were as follows

| | Mile | Kilometer | Miles an Hour |
|---|---|---|---|
| Brasier Despujols | 2 20 | | 25 71 |
| Brasier-Despujols | | 50 2-5 sec | 44 35 |
| Ursula | 2 36 2-5 | | 22 88 |
| Ursula | | 55 2 5 sec | 40 35 |

The Ursula this year is fitted with the same two 12-cylinder Wolseley Siddeley motors that were used last year As her best speed then was about 37 miles per hour it is fair to assume that the figures given in the cabled reports are not correct or else that the distances around the course were less than supposed It is extremely doubtful if the Duke of Westminster's racer averaged more than this figure in the long races especially since she made only 40 35 miles an hour in the flying kilometer speed trial We understand that on account of the great depth of the water where the races are held there is often times a shifting of the buoys owing to the inclining of the anchor lines and that this causes a shortening of the course The mile and kilometer tests are therefore the only ones in which any great degree of accuracy is obtained, and as experience has shown that in a long-distance race a boat will make less speed if anything, than in a short speed trial, it seems certain that the Ursula' has not shown much more than 40 miles an hour so far That she should have averaged 42 miles an hour with the same power plant as heretofore is very creditable

### An Aeroplane Flight with Five Persons, and Cross-Country Flying in France.

One of the most remarkable performances ever made with an aeroplane was that of Roger Sommer's new biplane last week in France when piloted by its constructor it carried him and four other persons in a five-minute cross country flight On this occasion the aeroplane lifted some 750 pounds of dead weight or probably a total weight of 1 800 pounds with presumably a 50-horse power motor

Another demonstration of the development of the heavier than air machine was given on April 18th by Louis Paulhan who flew from Orleans to Arcis-sur-Aube (118 miles) in 3½ hours on his Farman biplane The next day he flew 43½ miles farther across country in 1 hour and 10 minutes reaching a height of 750 feet Henry Farman on the 17th instant also flew 40 miles across country with a passenger

These brilliant flights form an ocular demonstration of the great advance recently made in dynamic flight and point the way to the practical utilization of the aeroplane for the transportation of individuals and of mail

The Electrical World states that at a recent miners' convention in Indianapolis the opposition of mine workers to electric power the introduction of which they consider against their interests was manifested in a resolution declaring that the use of electricity in mines is hazardous as the leakage from poorly insulated wires has a tendency to ignite mine gases and frequently causes explosions

# THE MANUFACTURE OF CELLULOID

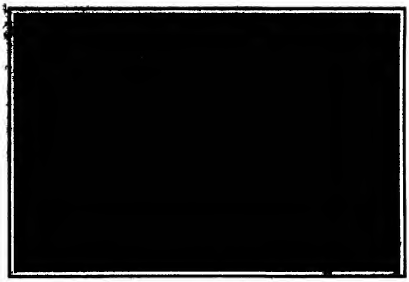
BY JACQUES BOYER

More than sixty years ago chemists began the search for substances of which imitations of horn tortoise shell, and ivory could be made One of the first ex perimenters Dr Pierson of New Orleans furnished a theoretical solution of the problem in 1848 by the discovery of celluloid a complex substance consist ing chiefly of nitrocellulose and camphor but no industrial application of celluloid was made until a much later date

In 1863 Parkes of Birmingham obtained a similar substance which he named 'parkesine by mixing guncotton with wood naphtha The hardness of parkesine limited its applications and it was employed chiefly as an electrical insulator In order to soften it caster oil was added to the mixture and afterward the naphtha was replaced by methyl alcohol Parkesine obtained a temporary success in England but it was driven out of the market by the cheaper celluloid the manufacture of which was begun by the Hyatt brothers in Newark New Jersey in 1867 Other large celluloid factories were subsequently es tablished in America France England and Germany

Celluloid is now made from a very pure form of cellulose usually obtained from cotton or unsized fil ter paper The cellulose is converted into nitrocellu lose by methods which vary somewhat in different fac tories Among the processes most commonly used is the following The material—raw or spun cotton or paper chopped or cut into strips—is immersed in nitr c acid for a period ranging from fiftee n i utes to two hours according to the chara ter of th fib rs and th temperature of the bath The cotton or paper now converted into nitrocellulose is taken out wrung and pressed to remove most of the adhering liquid which may or may not be returned to the itrating bath In either case the strength of the bath is r stor d to its original value by the addit on of con entrated nitric acid

The nitrocellulose is washed in water and ground in a paper mill in which a rotary movement is impressed upon the mass as it is forced between a pla a d two cylinders which rotate at a speed of 160 revolutions



Bending celluloid hairpins.

Blowing celluloid dolls.

THE MANUFACTURE OF CELLULOID.

per minute The cylinders are set with steel blades, parallel to the axis, and the plate bears a number of steel blades, slightly inclined to those of the cylinders The finely ground nitrocellulose next goes to the bleachery, where it is treated with chlorine, hydrogen dioxide sulphurous acid, potassium permanganate and other decolorizing agents It is then washed thoroughly, pressed between rollers, and dried

Celluloid is made by dissolving nitrocellulose in an alcoholic solution of camphor Some manufacturers mix the camphor with the moist product of the roller presses which contains 40 per cent of water, while others add the camphor to the dried nitrocellulose In the former case the moist pulp, camphor and coloring matter are ground together between horizontal, circularly fluted iron "millstones" The mixture is passed several times through this mill, and is then dried When the nitrocellulose is dried separately the lumps formed in the passage through the roller press are crushed by rubbing the pulp, with the hand through a coarse wire screen

Drying is effected indirectly by pressing the pulp between layers of absorbent material The pulp is spread on a cloth which is turned up over it, forming a rectangular cake 24 inches long 20 inches wide, and about ¾ inch thick. In the factory of the Société Industrielle du Celluloid these cakes are piled alternately with dry felts a sheet of iron being introduced after each ten or fifteen cakes, in order to facilitate handling The pile is then subjected to a hydraulic pressure of about 250 tons. After a few minutes of this violent compression, the now wet felts are replaced by dry felts and the operation is repeated until the nitrocellulose is dry The compressed cakes are now unwrapped and broken into fragments for solution If the camphor has been added before drying the broken cakes are simply sprinkled with alcohol, but if the dried nitrocellulose contains no camphor it is moistened with a solution of 90 parts by weight of camphor in 100 parts of alcohol

The solvent is allowed to act for 24 hours and then the mass is rolled between hollow iron cylinders, from 12 to 26 inches in diameter, which make 10 revolutions per minute, and are cooled or heated, as desired by a circulation of cold water or steam in their interior From 65 to 130 pounds of celluloid are rolled at a time the rolling being continued from half an hour to several hours Toward the end of the operation the cylinders are brought close together in order to produce a thin sheet of celluloid longer and wider than the press by which the sheets are converted into blocks The rolled sheets are trimmed to the exact dimensions of the press, and the trimmings go back to the rolling mill

In the Champigneul block press a strong iron box 54 inches long, 26 inches wide and 12 inches high is filled with sheets of celluloid and these are converted into a single block by pressing between two iron plates The top plate is fixed in position, while the bottom plate is carried by a plunger which enters a cylinder below and is forced upward by hydraulic pressure A pressure of 250 tons is applied for a period varying from 5 to 12 hours, during which the celluloid is kept at temperature of from 158 to 194 deg F by a circulation of hot water in the interior of the plates and the double walls of the box The mass is cooled by substituting cold for hot water the pressure being continued during the cooling The top plate is then removed and the block of celluloid is forced out of the top of the box by again applying pressure from below

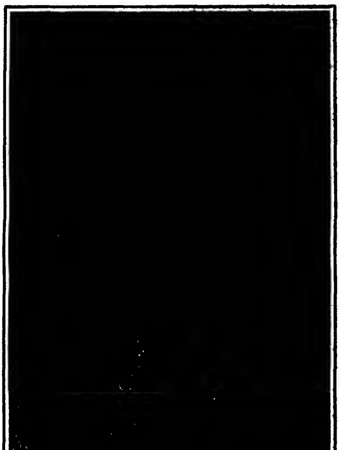
The blocks are cut into bands or rods according to the purpose for which the celluloid is to be used The bands are cut by a machine in which a knife, the edge of which is inclined 40 degrees to the horizontal, is forced downward by a screw In this way bands varying in thickness from 1/250 inch to 1¼ inch can be obtained. Celluloid is cut into rods or fibers by a machine in which the cutting tool has the form of a short cylinder of diameter varying according to the size of rod desired

The celluloid, after it is cut up is dried in chambers where the temperature is never allowed to exceed 113 deg F on account of the danger of explosion The time required for desiccation varies greatly with the thickness of the bands or rods Bands thinner than 1/100 inch dry in a few hours while strips thick enough to be used in making knife handles, for example must remain in the drying chambers about six months.

Tubes of celluloid are made directly from the rolled sheets in an apparatus which comprises two vertical cylinders, with their axes in the same line and their pistons connected by a stout rod. The bottom of the lower cylinder has a central orifice, to which annular apertures of various dimensions can be adjusted, and the lower part of the cylinder is heated by a circulation of hot water. The celluloid is introduced into this cylinder and hydraulic pressure is applied by means of the cylinder above. The celluloid, softened by the heat, is thus forced through the aperture in the form of a tube, which the operator draws away and cuts into convenient lengths by means of a clamp attached to a cord passing over reversible pulleys.

To return to the bands of celluloid which have been cut from the pressed blocks. In the drying chambers these bands become warped. They are flattened in a hydraulic polishing press which exerts a pressure of about 1,000 tons. The celluloid bands are piled alternately with sheets of polished brass or nickel-plated steel, a thick plate of cast iron covered with cloth or felt being inserted after each four or five bands. These iron plates contain channels for the circulation of steam or cold water While the pressure is applied the plates are first heated by steam to 180 or 190 deg F for a few minutes and are then cooled by cold water When the bands are taken from the press they are found to have acquired the high polish of the sheets of metal which were in contact with them.

Before describing the subsequent transformations of the bands rods and tubes of celluloid, the method of producing striped, veined, and marbled effects should be noted For this purpose two blocks of celluloid of different colors are made separately in the block press and cut into bands about 1/100 inch thick A pile of these bands, arranged in alternating colors, is sliced with a powerful paper knife. The fine strips of celluloid of two colors resulting from this operation are arranged regularly or irregularly in the block press and converted into a solid block of striped, veined, marbled or "watered" appearance



Flattening celluloid bands that have warped in drying.

THE MANUFACTURE OF CELLULOID.

From the bands, rods and tubes of plain and variegated celluloid, objects of every form and character, presenting the appearance of ivory, tortoise shell, mahogany and other woods, coral, amber, jade, malachite, silken fabrics, etc, are made by various operations, of which the most important are shaping, cutting out molding, curving, blowing, varnishing and decorating.

Celluloid, like wood, horn and ivory, is usually shaped by hand, with the chisel, drawing knife, rasp, etc. Celluloid hair pins are pointed on the emery wheel Shaping is done also on the lathe in the factory of the Société Industrielle du Celluloid. The cutting out is done preferably by machine, with punches, circular and band saws, and cutting wheels with straight and fluted edges. A wheel of special form is employed to cut out pairs of interlocking combs, which are finished on lathes and molding and other machines. Fine objects with curved [illegible] are cut out with [illegible]

[illegible] of celluloid [illegible]

Curving is effected by taking advantage of the plasticity which celluloid acquires on being gently heated. Celluloid hair pins, for example, are immersed in hot water, bent by hand on a metal form and then hardened by being plunged into cold water. These operations must be performed with skill and care, as celluloid becomes white and opaque when heated too strongly.

Celluloid objects of the utmost variety of form are produced by molding, in which operation the softening influence of heat is again utilized. The object, approximately shaped by other methods, is inserted between the two segments of a bronze mold, which are in contact with the heated plates of a steam press. When the celluloid has become sufficiently plastic, the plates are forced together, and the celluloid assumes the exact form of the mold, which it retains after cooling. Leaves, petals of flowers, and similar small thin objects of celluloid are shaped by stamping with dies.

The operation of blowing is performed on celluloid tubes as they are drawn from the press. A tube of suitable dimensions is placed in a heated mold composed of two or more segments and, when soft, is inflated by a blast of high pressure steam which forces the celluloid into contact with every part of the mold, which is cooled before opening. In this way whisk broom covers and similar cup-shaped objects, as well as dolls, animal figures and other toys are made The parts of celluloid boxes and other built-up objects are sometimes joined by means of acetone, acetic acid or other solvents of celluloid. Cheap boxes are varnished with a solution of celluloid in acetic acid, which saves polishing with pumice stone.

For decorating the surface of celluloid, aniline colors dissolved in alcohol are employed.

### Air Resistance Experiments.

A useful critical comparison of the work of Frank and Eiffel is presented by W. Schule in the Zeitschrift des Vereines Deutsch Ing The law that resistance is proportionate to the square of the velocity has been verified by Frank for velocities up to 6 m./sec, and by Eiffel from 15 to 40 m./sec. The specific resistance is proportional to the normal area, and this resistance does not reach its maximum with an area of 1 sq. m (Eiffel). The results of Frank for right circular cylinders and cones of various angles are in contradiction to those of Eiffel The error is considered to be on the side of Eiffel, and further, the resistance deduced by the latter from his experiments with inclined plates requires substantial correction. The resistance of an inclined plate increases very quickly with the inclination of the plate up to 30 deg., and much more slowly thereafter. Frank's coefficient for the surface friction of plates moving parallel to their length, viz., 0.00344, shows that the resistance of such a plate is 236 times less than that for the same plate moving along the normal. This coefficient agrees well with the resistance coefficient of vapors and gases in motion through tubes. In the region from 10 deg. to 0 deg. plate inclination, the surface friction is of prime influence on the specific resistance. Employing Frank's law of friction along with Eiffel's results for plates inclined at 20 deg. to 30 deg., the air resistance may be found for the region of most importance in flying technique, viz., between 0 deg. and 15 deg., at 5 deg. inclination, the resistance R, referred to the unit of surface projection, passes through a minimum value (k min. = 0.1 in the formula R = k × area × air density × velocity²/g). Air-resistance is composed of three parts—the acceleration resistance, and friction, external and internal. External friction only becomes of importance for angles of 15 deg. inclination and less. The direction of the resultant thrust on a plane surface only begins to deviate from the normal for plate inclinations of 5 deg. and less; for 5 deg. the deviation is 4 deg. from the normal, and for 1 deg. it is 24 deg. The ratio of upthrust to moving force for an inclined plate in motion is greatest for an inclination of 5 deg., and the [illegible] upthrust reaches a maximum for the angle [illegible]

## TELESCOPE LENSES AND HOW TO TEST THEM.

BY PROF. S. A. MITCHELL, COLUMBIA UNIVERSITY.

The arrival of Halley's comet and the interesting changes in its appearance noticed by the keen-eyed astronomer using a powerful telescope have naturally caused the uninitiated to inquire into the use of these glasses, and to wonder how much their eyes could see if a telescope were put at their disposal. Certain

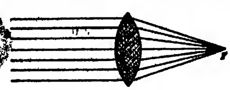

Fig 1.—FOCUS OF A LENS.

it is that the first look through a large telescope would be disappointing, for nothing appears as big or as magnified as expected. The beginner is apt to believe that he could see the whole moon at once and as if only a few miles away, but is amazed to find he can see only a small portion of it and that shimmering and dancing in a purple haze. He may admire the beauty of the color not knowing that this is caused by an imperfection of the telescope which cannot, unfortunately, be got rid of. Indeed, the moon presents a prettier picture in a three- or four-inch telescope than it does in anything bigger It is in the hope of explaining the simple things about a telescope that this article is written.

It is sometimes thought that a telescope is powerful because the rays of light pass through a large number of lenses placed at intervals down the tube This idea, like many another popular one, is entirely erroneous The telescope gets its power mainly from the objective which causes the rays of light coming from the object under observation to converge, and if not intercepted form an image

The action of a simple lens is easily understood. If parallel rays of light fall on the lens in the same direction as the axis of the lens they will (Fig 1) converge to a point *F*, called the principal focus, and similarly, rays from *F* will emerge as a parallel beam. *F* may be on either side of the lens, and it is imma-

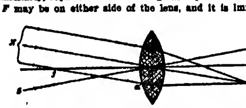

Fig. 2.—FORMATION OF AN INVERTED IMAGE.

terial in which direction the light goes through The distance from *F* to the lens is the focal length. Next, if we have a parallel beam not in the direction of the axis (Fig. 2). It will likewise converge to a point, different from *F* If we neglect the thickness of the lens, a ray through the center of the lens *C* will pass through undeviated, a ray *fn* through *f* the focus will emerge parallel to the axis. Rays from the north of the moon, *N*, will be brought to a focus at *n*, and from the south edge of the moon, *S*, to the point *s*. Hence the lens forms a real image at the focus, so that if we placed there a ground-glass or a photographic plate we would obtain a picture of the moon This image is *inverted*.

Three different ways of using the convergent pencil of rays from the object glass give three different kinds of telescopes. If the rays before they came to a focus fall upon a double concave lens we have the Galilean telescope, a principle which exists in the modern opera glass. This gives an erect image. If the image at the focus is examined with a double convex lens, a "magnifying glass," we have the astronomical telescope, first invented by Kepler. This gives an inverted image. If the image is examined by three double convex lenses, a compound microscope which again inverts the images, there results the terrestrial telescope, and objects are seen erect.

In the century following Galileo, telescopes were made of enormous length, frequently being over one hundred feet long, and one was made with a focal length as great as 600 feet. The older opticians had found that if they attempted to increase the size of the objective, it was necessary to still more increase [illegible] to obtain a clear field. The [illegible] are plain; rays falling on the middle of a simple lens are brought to a focus at a different point from those falling on the edge of the lens, as is shown in Fig. 3. The distance from *F* to *G* gives the amount of the "spherical aberration." Even more trouble was caused by the "chromatic aberration," the

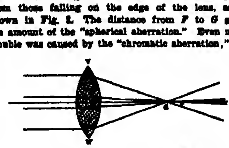

Fig. 3.—SPHERICAL ABERRATION.

star images had a great amount of color surrounding them. A lens may be regarded as a round prism Since a prism not only deviates light but breaks it up into the spectrum colors, a simple lens will act as is shown in Fig. 4, the violet light is most refracted and is brought to a focus at *v*, the less refrangible red comes to a focus at *R*, with rays of the other colors in between these two extremes. The result of all this is that if we focus for the yellow, the red and violet form rings around this and a star image is surrounded with a considerable amount of color Sir Isaac Newton was the first to explain these aberrations, and it is singular that although he made experiments to prove that glass and water disperse light differently, he did not forestall Dolland's discovery (150 years ago) of making an objective from a combination of two lenses, one a double convex lens of crown glass, the other a double concave lens of flint glass.

With such a combination the optician has four surfaces to figure, and as a result it is possible to almost entirely eliminate the spherical aberration, or in others words make a flat field But on the other hand it is still impossible to get entirely rid of color Flint

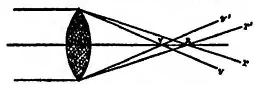

Fig 4.—CHROMATIC ABERRATION.

and crown glass do not disperse light alike, the flint relatively widens out the violet end the more The optician with glass of two different sorts at his disposal can bring two colors of the spectrum to a sharp focus For a visual telescope the rays generally taken are the yellow and the blue green Consequently both the red and the violet ends of the spectrum are not in sharp focus, and these form rings about the stellar image which combine to make purple color In small telescopes this color is not so pronounced, but with large telescopes of 24 inches or more aperture the color is conspicuous and cannot be got rid of This is known as the "secondary spectrum"

The problem of making a good visual lens is really a much simpler one than that of making a good photographic one. In the first place, in the ordinary telescope for visual purposes, the field is comparatively small, of only a few minutes of arc, and the process of making a field flat over the area is simple compared with that required in an instrument like the Bruce photographic telescope of the Yerkes Observatory, which photographs an area in the sky 16 deg square. With refracting telescopes the ratio of aperture to focal length is about in the ratio of 1 15 (the Yerkes 40-inch has a focal length of about 750 inches, a ratio of nearly 1 . 19). In a photographic telescope,

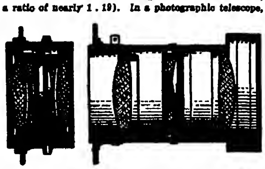

Fig. 5.—COMBINATIONS OF LENSES FOR RAPID PHOTOGRAPHIC WORK.

for the portrayal of a comet, for instance, as short exposures as possible are desired, and this calls for as great a ratio of aperture to focal length as possible. The ordinary amateur's camera works very well at a ratio of aperture to focal length of 1 16 If the lens is opened to 1 · 8 the photograph is not so sharp. Only lenses of the best makes can be used at 1 : 6. (Fig. 5.) Everyone who is familiar with the use of a camera knows how much sharper a picture is obtained by stopping down the lens. To obtain a flat field from a lens with an aperture of 1 6 is impossible with only two lenses; three or more are necessary Using glass of different indices of refraction which is possible from the fine qualities of Jena glass now procurable, separating the lenses properly and grinding their surfaces to the right curves, it is possible to obtain a flat field with an absence of color and astigmatism. (Fig 6.) The Bruce photographic telescope has an aperture of 10 inches with focus 50 inches It is a 4-lens combination, technically known as a "doublet"

Every skillful amateur knows how to test a photographic lens. This is perhaps done as well as any other way by the test cards for astigmatism, to see

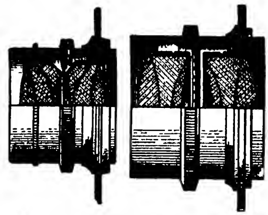

Fig 6.—COMBINATIONS OF LENSES FOR FLAT FIELD AND ABSENCE OF COLOR.

if straight lines which intersect at right angles become lines or blurred images at the edge of the field. Still a lens might answer all the requirements for ordinary camera work but be a poor astronomical lens. A camera might cut clear to the edge of the plate on ordinary work, but when a three or four-hour exposure is given on stars all imperfections will show up Unfortunately, for obtaining astronomical photographs a telescope mounting with a good driving clock is indispensable—which is usually out of the reach of most amateurs

On the other hand there are a number of small visual telescopes in the hands of amateurs, and a few words might be said in regard to testing them This is best done on a moderately bright star Focus carefully on it Push the eyepiece in slowly and note the change in appearance If the spot of light does not remain circular, the objective is not "squared on" properly, or the objective may be pinched in its cell This must be adjusted before anything more is done Now pushing the eyepiece in, the colors should

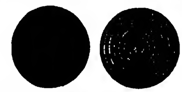

Fig 7.—WORK OF A RECTILINEAR LENS COMPARED WITH AN ANASTIGMAT BLURRING DUE TO ASTIGMATISM IN RECTILINEAR LENS.

change gradually and symmetrically as the disk of light enlarges The same should hold true by pulling the eyepiece outside the focus If the telescope behaves well from this test, turn to a double star like Castor As the amateur becomes familiar with the heavens, he will soon learn test objects for his telescope, and if he possesses a good instrument there is no keener pleasure than trying it night after night and becoming familiar with the beauties of the heavens.

## POWDER PLATING OF METALS.

Before a meeting of the Royal Society of Arts, in London last January, a paper was read on an improved method of electro-plating It described the process of plating metals by rubbing them with a moistened powder, and a number of articles were plated with gold silver and zinc before the society. The new plating powders are not to be confused with plating preparations which have been in use heretofore and which act merely to exchange the surface metal of the article to be plated with a thin film of deposited metal. In the new process a truly electrolytic action takes place which results in the deposit of metal without taking away the surface metal from the object to be coated Furthermore the deposit may be made as thick as desired by continued applications of the powder The inventor of this plating powder began his experiments a number of years ago with a view to developing a process by which knives forks spoons and the like can be plated as readily as they can be cleaned with polishing powders, and he succeeded in devising a method by which almost any

metal and even certain alloys such as brass in various proportions of copper and zinc can be applied to metal objects So far the new powders are not on the market in this country but in England they are sold in small cans for a shilling each and one can is sufficient to plate the nickeled portions of a bicycle or to plate a quantity of household silverware

The powders are composed (1) of the metal to be deposited in its elementary state (2) of a salt preferably a salt of ammonia and (3) of a powdered metal which must be electropositive to the metal which is to be deposited Magnesium is the most electropositive metal which it is commercially practical to use and in many of the preparations this forms the active element In some of the preparations aluminium and zinc are used The following formula gives the zinc plating powder

| | |
|---|---|
| Zinc | 15 parts by weight |
| Ammonium sulphate | 5 parts by weight |
| Magnesium | 1 part by weight |
| Chalk | 10 parts by weight |
| Soapstone | 25 parts by weight |

Ordinary commercial zinc dust even though it is not perfectly pure may be used This same formula may be used for several other metals If silver be substituted for the zinc in this formula a very heavy deposit will be obtained which will have the white frosted appearance of silver electroplating before burnishing If gold is substituted for the zinc the deposit will be a light yellow but various shades down to a rich red have been obtained by varying the formula The article which is to be plated with the powder does not have to be cleaned before the powder is applied for the powder itself acts as a cleaning powder and liberates the oxygen of an oxidized surface The amateur who wishes to experiment with these powders should bear in mind that they have been patented abroad and that patents are pending in this country

## MAKING MILK ARTIFICIALLY

BY A. J. JARMAN

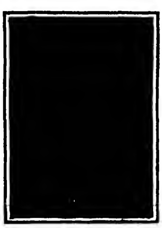
We have heard so much about the synthetic production of perfumes syrups dyes and what not from coal tar products that we are not easily surprised by the information that milk may be artificially made The method described below however is not a chemical one but consists merely in the mechanical admixture of distilled water with crushed and finely ground sweet almonds Practically the only difference between cow's milk and that made of almonds is that cow's milk contains animal casein while the artificial milk contains vegetable casein The latter will produce a good supply of cream and if allowed to stand some time will become sour It may also be coagulated by the addition of vinegar or acetic acid When combined with grape sugar it is capable of generating some extraordinary organic substances The artificial milk may be used with tea and coffee in the same way that cow's milk is used

To make the milk procure half a pound of sweet almonds—the Valencia which is cheaper than the Jordan almond will give just as good results The skin of the almonds may be removed by scalding the nuts in boiling water and peeling them with a sharp knife The almonds should then be placed in a wooden chopping bowl and chopped as finely as possible Take about two ounces of the chopped almonds and place them in a mortar with a small quantity of distilled water Then grind or levigate the chopped almonds adding water occasionally until about twelve ounces of water have been used The longer the grinding is continued the thicker and richer will the milk be Now take a piece of cheese cloth about 12 inches wide by 24 inches long and rinse it in clean water and after wringing it as dry as possible fold it double over the top of a pitcher and pour the contents of the mortar through the cloth into the pitcher The milk may be squeezed through the cloth by wringing it gently as shown in one of the illustrations, but care should be taken to prevent any of the larger almond particles from being forced through the meshes of the cloth

If some of the milk thus produced is set aside for three or four hours a thick layer of cream will be found on the surface If too much water has been used in forming the milk it may be necessary to add a little sugar of milk to sweeten it The artificial milk has a slight almond flavor when taken clear but this is practically lost when it is used with tea coffee or cocoa The color of the cream produced is quite pale but it may be improved by using some of the almonds without the skins removed in the proportion of two ounces of whole almonds to six ounces of the blanched almonds Care must be taken to prevent any bitter almonds from finding their way into the mixture but one or two bitter almonds to half a pound would not affect the flavor of the milk

Half a pound of almonds will make three pints of milk

Chopping the almonds.



Grinding the almonds in water.

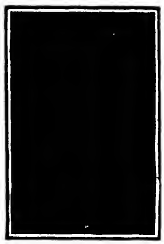
Filtering the almond milk.

MAKING MILK ARTIFICIALLY

## SOME EXTRAORDINARY DENSITIES

BY [illegible]

Pick up any common heavy stone such as granite or compact limestone Lay it at the bottom of a vessel filled with a fluid transparent liquid Common sense tells you that the stone will stay there Modern



A COMMON HEAVY STONE FLOATING IN A GLASSFUL OF BROMOFORM

chemistry tells us that if the liquid has been selected for such a purpose the stone will spring up to the surface as if it had been forced into mercury instead of being immersed in what seems to be water

Liquids which are denser than glass marble or common stones are not numerous Leaving aside the metals mercury and gallium and the metalloid bromine which is opaque caustic and emits suffocating vapors the most interesting of such liquids are the aqueous solutions of the tungstoborates Their densities reach 3 3 (saturated solution of cadmium tungstoborate) An idea of the meaning of such a number can be gathered from the fact that a man with his shoes weighted so as to lower his center of gravity could stand erect in such a solution with more than half of his body out of it The chemist Klein who studied the tungstoborates proposed to use them for the sorting of ores and other minerals as in most cases useful or precious stones only will go to the bottom of their solutions Their price however (the saturated solution of cadmium tungstoborate is sold at two cents a gramme) will for some time to come preclude such an application

Solid aluminium remains on the surface of such liquids To see a metal floating over a watery fluid is however no new spectacle for the chemist, several [illegible] of the other metals being lighter than water. The cheapest of these [illegible] the experiment should not be made with a piece larger than a [illegible], for it is sometimes attended with unexpected explosions and projections of caustic soda. As a rule, however, the metal runs swiftly and quietly over the water while decomposing it.

Sodium is the cheapest of the extremely light metals, but it is not the lightest. Lithium, a beautiful metal of a silvery white color, is lighter than dry pine wood Yet, from the chemical standpoint, it is more metallic in its properties than the heavy osmium which occupies the other extreme position in the list of solid elements arranged according to their increasing densities.

Such extreme differences in density are not found among liquids yet organic chemistry gives us two colorless transparent liquids which so differ that a vessel filled with the lighter of them amyl hydride or pentane and easily carried by one man, could not be lifted by four men when filled with bromoform The density of pentane is 0 6 that of bromoform 2 9 Both liquids are apparently more fluid than water and it is always amusing to watch the countenance of the unaware person who is requested to remove a glass full of bromoform from one place to another Bromoform is sometimes prescribed by physicians against whooping cough It is found at every drug store and costs but $1 75 a pound

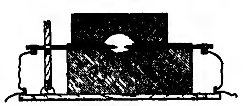
But it is with gases that the greatest divergences in density occur Iodoform vapor which causes the intense stench of that well known antiseptic is 197 times heavier than hydrogen When some iodoform is vaporized in a porcelain dish placed over an alcohol or gas lamp it is partially decomposed Iodine vapor is set free and remains mixed with iodoform vapor As iodine vapor is itself one of the heaviest of gases the experiment remains very beautiful If the air is quiet a lateral jerk given to the dish causes the layer of violet gas to oscillate heavily just as a liquid would do in similar circumstances

## A SMALL ELECTRIC FURNACE.

BY A. E. PARKINS

The accompanying cut shows the cross section of a small electric furnace made from a description of the Moissan furnace In this one the brick and lime cavity are replaced by a block of limestone about 5 x 5 x 3 inches In the top face of the base is hewn a cavity about 1 x 1 x 2 inches also two longitudinal grooves to receive the carbon electrodes

The cover is a similar stone with a cavity hewn in its lower face Both base and cover should be bound with a piece of sheet iron or tin to keep the pieces in place should the heat be great enough to crack the stones The carbons are regulated by means of the vertical lever hinged at the base and attached to the carbon by means of a clamp This clamp is attached to the lever at one place only This allows



A SMALL ELECTRIC FURNACE

sufficient horizontal movement The electrodes are connected to a lantern circuit (alternating current 212 volts) by means of clamps These clamps and other metal work are made from sheet aluminium—easy to cut and easy to shape. The bolts used are short stove bolts

In such a contrivance calcium carbide calcium phosphate phosphorus brass and alloys are easily prepared

Calcium carbide requires intense heat, the cavity should be small Gas carbon or powdered arc light carbon is best to use

Calcium phosphide is prepared by heating calcium oxide carbon and red phosphorus The phosphorus is placed in first in small quantities this is covered by the other ingredients well mixed and pulverized Some kinds of animal charcoal and calcium oxide will produce calcium phosphide

Phosphorus is prepared as directed in Newell by heating a phosphate, charcoal and sand Phosphorus is separated and burns at the top It sometimes sublimes on the faces of the stones and bursts into flame when the cover is lifted The glass like slag remains in the furnace This is exceedingly hot. Pieces of porcelain are easily melted when pushed into this plastic mass

Brass is easily made by heating zinc and copper. The stones may be obtained from the refuse heap of a stone cutter's. The corner of an old [illegible] will prove a good instrument for [illegible] School Science and [illegible]

### NEW BOOKS, ETC.

SCIENTIFIC AMERICAN HAND BOOK OF TRAVEL. With Hints for the Ocean Voyage, for European Tours, and a Practical Guide to London and Paris. Compiled and Edited by Albert A. Hopkins, Editor of the SCIENTIFIC AMERICAN Reference Book. New York: Munn & Co., Inc., 1910. 16mo.; 500 pp.; 500 illustrations. Price, $2 net in flexible cloth; full leather, $2.50 net.

There are no conditions of travel in which a few general hints as to how to adjust one's affairs can prove so useful as on a sea voyage, and it is with the object of preparing the traveler for his trip by telling him how to go, how much it will cost, how to amuse himself, and what to do when arriving at the coveted shore, that this book has been written. It is the result of twenty years' investigation and travel on the part of the Editor, who is a member of the staff of the SCIENTIFIC AMERICAN. The work contains six color plates and an elaborate set of maps in a pocket in the back of the book, including an excellent touring map of Europe published by the Automobile Club of America. The maps of London and Paris are on a new plan. The illustrations were selected from over 5,000 which were placed at the disposal of the Editor, and many of the scenes on shipboard have never before been reproduced. The book is of a convenient size to be carried in the pocket and is a handsome piece of book making. The writer gives the kind of information which he himself and others of his acquaintance have wanted to know on various transatlantic voyages. Much of the material presented is in so readable a form that pages can be read by the score, which is something unusual in a guide book or similar book of reference. Thus it tells how the circuit of the earth can be made in thirty-eight days, instead of the proverbial eighty days of Jules Verne, it tells how it is possible to leave New York Wednesday morning and reach London Monday night and Paris Tuesday morning. The book is so extensive that it is impossible to do more than call attention to a few of the salient features. The question of time is admirably dealt with, and the elucidation of the twenty four-hour clocks used in Berlin, Italy, and Spain is of particular value. The traveler's vocabulary in four languages precludes the necessity of the purchase of special books on the subject, as does also the cable code. The question of expenses is dealt with in detail, while the much vexed question of baggage is considered at some length. Various ocean fares are given, as well as information as to how to carry money. The sizes of foreign coins are given by means of diagrams, which will prevent much confusion in the minds of those who use foreign coins for the first time. The list of articles not to be forgotten is one of the interesting features of the book. The section relating to telegraphs and cables is absolutely complete, and is indorsed by the officials of all the leading telegraph and cable companies. "The Voyage" is dealt with in detail from the time of coming on board until the landing on the foreign shore. The smallest thing which can help, interest, or amuse the traveler will be found in the proper place; thus, for the concerts there is given "America," "Star-Spangled Banner," "God Save the King," "Rule Britannia," "Marseillaise," and the "Watch on the Rhine," which are all of the national anthems of four countries that are usually played. The question of seasickness is the subject of some three pages, and the best and most successful remedies are given. The technical portion relating to the ship deals with everything from the keel to the lookout, and is accompanied by interesting engravings, many of which were made specially for the book. The section on "Ocean and Navigation" deals with the work of the officers and describes the many interesting things which are met with, such as icebergs, whales, etc., and the amount of nautical lore conveyed is considerable. Everything relating to signals is presented. The section relative to statistical information offered peculiar difficulties which have been surmounted in a masterly manner. Thus the list of transatlantic passenger steamers is given which sail not only from New York, but from such minor ports as Galveston. There are maps of all the harbors in the United States from which steamers arrive and depart for both Europe and Asia. The railroads of the world, distances in nautical miles between ports and lights are also given. The section devoted to "The Arrival" is a highly important one, dealing with all of the principal terminal ports and ports of call. The book even tells the visitor how to get to Hoboken. The section relating to "Railways" gives much-needed information which cannot be obtained elsewhere in the English language. The part of the book devoted to Tours occupies thirty-four pages, and gives 450 tours with prices. There is also a list of 2,000 hotels and their rates, and a most valuable chapter on automobiling in Europe, which has been unqualifiedly indorsed by the leading automobile clubs and associations. The Guide to London was written by the English correspondent of the SCIENTIFIC AMERICAN, Mr. F. A. A. Talbot, who is well known to our readers, and is without exception the most up-to-date guide to the great British metropolis. The practical guide [illegible] [illegible]

not thinking of taking a European trip will find the book of the utmost value as a work of reference.

### RECENTLY PATENTED INVENTIONS.

#### Electrical Devices.

ELECTRIC VENTILATOR.—W. MERLHOSS, Charlottenburg, Germany. The invention relates to a ventilator consisting of an electromotor and two fans, one of which is fastened on the armature shaft of the electromotor, while the other fan is mounted on a suspended support to turn around a vertical axis and is adapted to carry within its bell-shaped nave the casing of the electromotor.

TRICK ELECTRIC POCKET LAMP.—A. JANAT, New York, N. Y. More particularly this invention relates to that type of apparatus in which a movable part may be unexpectedly released during the handling or manipulating of the device. One object is to construct the device so that it will have the exact appearance of a pocket electric light with the battery casing, light bulb and switch or push button.

#### Of Interest to Farmers.

ADJUSTABLE COMB FOR GRAIN-STRIPPING MACHINES.—E. A. A. PAVY, North Parade, Jamestown, South Australia, Australia. The comb is for use with strippers and stripper harvesting machines in which the adjustment is made by increasing or decreasing the width of the individual teeth. The purpose of the inventor is to enable the comb to be quickly adjusted to take a heavy or a light crop and also to enable a choke to be easily and quickly cleared.

BALE-TIE MACHINE.—J. A. SCHARF, Richwood, Ohio. An object of this improvement is to form a machine which will perform the various operations of drawing out, bending, twisting, stretching, cutting and removing the bale-ties from the machine, with a small amount of power and with the least attention from the operator.

#### Of General Interest.

ABDOMINAL RETRACTOR.—J. E. SPARKS, Crossett, Ark. The invention pertains more especially to abdominal retractors, although with suitable modifications the instrument may present a speculum for the parts, a rectal speculum or mouth gag, in any case, the feature of adjustment and automatic locking of the spreading arms being substantially the same.

GOPHER-TRAP.—A. F. RENKEN, Kramer, Neb. This invention refers to means for killing the pocket gopher, a type of field rat that closes the mouth of its burrow with earth that it pushes in front after a burrow is extended and widened sufficiently to permit the animal to turn around. This trap is adapted to kill this rodent by taking advantage of its peculiar habits.

#### Heating and Lighting.

COMBINED GAS AND ELECTRIC FIXTURE.—A. I. SCHWINGES, New York, N. Y. This fixture is in the form of a highly ornamental chain, having a continuous channel for the passage of the gas and an interrupted passage for the electric wires, to permit of conveniently threading the electric wires in the links of the chain and to give access to the wires at any time for repairs or other purposes.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending April 19, 1910,**

**AND EACH BEARING THAT DATE**

[See note at end of list about copies of these patents.]

Acid baths, apparatus for preparation of carbonic, J. Michal . . 955,182
Aeroplane, L. R. Culver . 955,289
Air brake, C. W. Frye . 955,788
Air brake controlling means for locomotive engines, S. N. Stevens . . . . 955,611
Air brake system, A. J. Wiener . . . . 955,695
Air compressor, automatic, J. Rogers . . 955,497
Air compressor, hydraulic, P. Bernstein . . 955,154
Alarm. See Fire alarm.
Alternator, exciting, C. H. Kirklighter . 955,171
Amalgamating apparatus, Montgomery & Wettam . 955,404
Amusement device, F. Jackson . 955,407
Anti-inductive device, M. M. Davis . 955,141
Antiskidding device, N. Barnett 955,306
Auger, A. M. Howland . 955,808
Automobile heater, D. J. Welton . 955,624
Axle, vehicle, C. Quinn . 955,201
Bag fastener, H. Vanderwerp . 955,693
Balancing device, H. R. Reed . 955,435
Balls, making hollow metallic, J. W. Schatz 955,698
Basket, E. O. Nelson . 955,824
Bearing ball, A. Riehle . 955,260
Bearing roller, W. J. Brewer . . . . 955,128
[illegible], I. E. Palmer . . 955,350
[illegible], electrical signal, H. W. Eden . . . 955,098
[illegible], W. S. Brown . . . 955,577
[illegible], E. L. Wilcox . 955,573
[illegible] . 955,307
[illegible], W. H. & L. K. Meacham 955,345
[illegible], T. F. Rooney 955,369
[illegible], A. L. K. Moyes . 955,348
[illegible] C. H. Clark . . [illegible]
[illegible] [illegible]
[illegible] [illegible]

Bottle, W. P. Bebler 955,309
Bottle and stopper therefor, W. Douglas 955,772
Bottle cap, A. Calleson 955,390
Bottle ends with tin foil, machine for closing, T. K. Keith 955,270
Bottle stopper, water, Schweinert & Kraft 955,441
Bottles and vessels, cap for, A. G. Kent 955,808
Bottling machine, S. Meinsberg 955,551
Box. See Mail box.
Box blank making machine, H. C. Stande 955,718
Brake beam, O. H. Williams, Jr. 955,239, 955,240
Brake beam, S. U. Walch 955,620
Breeder, H. A. Nourse 955,473
Brush holder, paint, O. H. Jorey 955,646
Brushes, bristle rim for rotary, I. Abrahamsohn 955,738
Building blocks and wall, H. Van Canyseele 955,380
Butter tester, O. Wagner 955,725
Cabinet, kitchen, J. M. Raimer 955,746
Cabinet, medicine, C. Reid 955,312
Cable clip, F. D. Ogden 955,559
Cable hauling engine, O. Potter 955,288
Camping apparatus, G. H. Crouk 955,140
Can feeding and delivering mechanism, J. W. White 955,731
Candy cooler, G. F. Dickson 955,771
Car brake operating mechanism, W. D. Brewster 955,490
Car, convertible stock, A. Westphal 955,238
Car door, H. A. Christy 955,281
Car door, A. R. Bullock 955,755
Car door, C. Buss 955,707
Car door supporting and operating means, flush, D. F. Noll 955,537
Car doors, weather and cinder strip for box, J. M. Jordan 955,516
Car, dumping railway, J. V. Ericson 955,453
Car fender, L. Fabian 955,147
Car fender, O. A. Bisbee 955,495
Car replacer, F. J. Wood 955,575
Car roof framework, R. Posson 955,544
Car safety brake, W. R. Nolan 955,536
Car step extension, Mitchell & Campbell 955,658
Car ventilator, R. Posson 955,543
Car wheel and propelling parts cooperating therewith, double safety, L. Clark 955,982
Car window, L. J. Berg 955,123
Cars, electric signaling device for motor, J. L. Pabens 955,192
Cars, life guard for railway, G. A. Parmenter 955,078
Cars, means for locking drop doors of dump, R. G. Taylor 955,228
Carbureter, J. W. Smith 955,218
Carbureter, A. B. Stoker 955,222
Carbureter, F. W. Michles et al 955,292
Carbureter, W. R. Park 955,353
Carriage, house moving, D. Sloot 955,221
Carriage top, G. W. Hedrick 955,512
Carrier. See Die carrier.
Cartridge, C. O. Person 955,640
Cash register system, P. H. Warnock 955,621
Caskets, etc., fastening device for burial, J. B. Muckle 955,665
Castor, E. H. Humphrey 955,162
Cellar storm and refrigerator, D. K. Harry 955,794
Centrifugal separator, Preston & Duffie 955,355
Chuck, drill, N. Drew 955,326
Churn dasher, R. A. Franklin 955,304
Cigarette tipping machine, individual, A. Boucher, reissue 13,105
Circuit closer, H. H. Cutler 955,325
Clip cap, J. W. Kessel 955,517
Clock, master, M. W. Obermiller 955,598
Closet ventilating and flushing apparatus, E. M. Laughear 955,318
Cloth holder, E. A. Spinney 955,219
Clothes drier, F. E. Bird 955,876
Clothes line clip, W. M. Fridall 955,237
Clothes rack, M. Redlinger 955,434
Coal and ore crusher, J. F. Bauerman 955,555
Coal dust, coal slack, and the like, semicoking, C. W. Buehler 955,310
Coat facing, E. Reisman 955,690
Coating metal objects, B. Hemann 955,693
Cock, stop and waste, W. H. Dunn 955,770
Coffee roaster, A. N. Tava 955,616
Coin operated key lock, C. E. Guthrie et al. 955,792
Collapsible tube, W. E. Morrison 955,530
Collar, coat, M. Koppelman, reissue 13,104
Combing machines, construction of and means for actuating the dabbers of wool, Boys & Tierney 955,782
Composing stick, B. A. Neldich 955,534
Composition of matter, Schmitt & Hell 955,269
Compressor, J. D. Mayhew 955,822
Concentrator, reciprocating multiple compartment, G. A. Fowler 955,329
Concrete building, W. S. Laney 955,097
Concrete construction, reinforced, E. P. Wells 955,286
Concrete curbs or gutters, form for laying, M. S. Hotchkiss 955,801
Concrete fence, reinforced, C. Mitchell 955,528
Concrete headstone, W. R. Thomas 955,720
Concrete mold, adjustable, H. Pocock 955,282
Concrete railway tie, W. H. Frays, Jr. 955,547
Concrete sidewalk form, Ramey & Chilcote 955,474
Concrete structural work, form for, M. S. Hotchkiss 955,800
Concrete tie, reinforced, C. R. Holden 955,615
Condenser and mold for carbon dioxid, W. J. Flemming 955,434
Cooker, fireless, J. Winter 955,735
Cooler. See Candy cooler.
Cooling apparatus, G. W. & H. A. Wise 955,242
Core, collapsible, S. A. Wellman 955,235
Corn husking and shredding machines, discharge spout for, A. Rosenthal 955,357
Cotton chopper or cultivator, M. C. Burck 955,706
Cotton folder, F. Phelps 955,542
Course indicator, H. H. Nebenas 955,847
Crayon holder, G. A. Tucker 955,817
Cue tipping machine, G. Mahoney 955,819
Cuff protector, N. Cerri 955,631
Cultivator, lister, W. S. Graham 955,810
Culverts, collapsible and adjustable mold for cement, G. W. Fish 955,779
Currycomb attachment, N. H. Burns . . 955,579
Curtain pole, E. F. Randolph . . . 955,697
Curtain roller, L. Rockand, Sr. . . . . [illegible]
Cushion, F. P. D'Arcy . . . . [illegible]
Cutting-off tool, L. J. Mahoney . . . . [illegible]

Cylinder press, E. P. King . 955,647
Dado machine, P. L. Billingsley 955,749
Decoy duck, J. W. Reynolds 955,256
Dental engine, electric, J. V. Tresaman 955,464
Dental lavatory, T. Dunbar 955,143
Dentimeter, A. D. Cloud 955,830
Desk and seat, school, A. R. Milner 955,184
Desk support, school, W. A. Proctor 955,546
Die carrier, H. Zimmerman 955,345
Disk marker, C. H. Myers, reissue 13,103
Display box fronts, fastener for, A. F. Urban 955,563
Display device, L. G. Quackenbos 955,200
Display rack, J. Weikerstorfer 955,734
Display rack, mattress, L. Emerich 955,595
Display rack or stand, J. D. Vassio 955,549
Distilling column, E. Bolton 955,127
Door and mechanism for operating the same, automatic, J. & J. Parkhill 955,040
Door for cold storage rooms, Flotron & Hamilton 955,792
Door guide, Crosby & McClouden 955,540
Door opening and closing device, T. M. Blackwell 955,125
Doors from sagging, device for preventing, P. M. Nordquist 955,074
Doors of hatches, means for operating, J. T. Taylor 955,681
Draft concentrator, P. J. Mooney 955,605
Draft mechanism, L. J. Jackson 955,805
Drainage plugs, operating mechanism for, H. J. Geurink 955,495
Drawer pull, S. R. Curtledge 955,760
Drawing press, W. Klock 955,173
Drier. See Clothes drier.
Drill socket, F. Mahr 955,650
Drumhead tightener, E. M. Yates 955,796
Dye, thioindigo vat, Schmidt & Thiess 955,099
Ear plug for bathers, J. Lopiatch 955,276
Egg beater, Nielsen & Imirie 955,672
Eggs, preserving, H. J. & H. C. Keith, Jr. 955,835
Elastic wheel, J. O. MacLachlan 955,417
Electric currents, apparatus for transmitting and utilizing, P. C. Hewitt 955,459
Electric currents, transmitting and utilizing, P. C. Hewitt 955,460
Electric furnace, Meyer & Stillesen 955,658
Electric machine, G. D. Holmgren 955,390
Electric terminal clip, W. Berry 955,747
Electrical conductor for illuminating purposes, I. Ladoff 955,373
Electrical conductors, device for preventing induction in, M. M. Davis 955,142
Electrical distributing board, R. J. Blakeslee 955,126
Electrical distribution, system of, J. L. Woodbridge 955,447
Electrical heater, E. Laws 955,598
Electrical receptacle, screw plug, F. J. Russell 955,435
Elevator safety device, C. J. Brookins 955,451
Elevator system, electrohydraulic, E. M. Fraser 955,508
Embroidery hoop, N. C. Leonard 955,415
Engines, current controlling mechanism for internal combustion, L. T. Rhoades 955,204
Engines, frame construction for gas, J. A. Charter 955,633
Engines, speed regulator and timer for explosive, J. F. Murphy 955,667
Excavating shovel, C. J. Reise 955,285
Exercising machine, electrical muscular, W. Harris 955,793
Extinguishing burning benzine, etc., M. Breslauer 955,318
Fan, mechanical, L. Mesnaros 955,823
Fan, oscillating, A. Rubin 955,210
Fastener, J. W. McKitrick 955,188
Faucet, W. H. Kilbourn 955,372
Faucet, H. Mueller 955,831
Faucet, J. Glelow 955,641
Feed bag for horses, C. W. Millsaps 955,182
Feeder, poultry, E. R. Donaldson 955,508
Fence clamp, wire, J. W. Davis 955,264
Fencing machine for reeling and cutting off wire, J. M. Denning 955,584
Fertilizer distributer, L. C. Butler 955,132, 955,133
Fertilizer distributer, C. H. Pelton 955,354
Filaments for incandescent lamps, manufacturing, J. W. Howell 955,461
Filter, G. Moore 955,660
Filter, F. D. Freeman 955,787
Filtering process, G. Moore 955,430
Fire alarm, J. H. Hayes 955,798
Firearm, C. A. Young 955,490
Fire escape, G. R. Wirt 955,343
Fireproofing compound, S. Gosnell 955,282
Fishing line reel and holder, W. F. Simms 955,300
Floor joist and ceiling combination, A. F. Leiter 955,398
Floor scraper, W. F. Stern 955,444
Flower pot and jacket for the same, G. Hershkovitz 955,644
Flue blower, F. Shmousky 955,706
Folding table, S. Hyde 955,804
Follower wheel, composite, H. H. Tunis 955,227
Forging press, T. F. Bally 955,122
Frames, attachment for testing or treating, H. C. Hill 955,553
Freezing apparatus for concentrating solutions by, H. Monti 955,600
Fryer, doughnut, B. W. Forgue 955,307
Funnel, L. N. Ritten 955,463
Furnace. See Electric furnace.
Furnace, L. B. Piper 955,190
Furnace, H. A. MacClymont 955,340
Furnace, W. G. Crosthwaite 955,387
Furnaces, hot blast for boiler, I. H. Bagley 955,578
Gage. See Rule gage.
Gage, W. A. Lomax 955,175
Garment closer, O. Bleichkramer 955,637
Garment supporter, H. I. Illin 955,837
Gas burner, P. L. Dean 955,300
Gas cleaner, P. Meehan 955,651
Gas generating apparatus, G. H. Eason 955,585
Gas producer, Stone & Dodd 955,614, 955,615
Gear fastening device, F. Meyer 955,658
Gear mechanism, reciprocating, W. L. Hamilton 955,331
Gearing, G. R. Pilkington 955,194
Gearing, K. Lippert 955,616
Gearing, automobile transmission, R. R. Wynn 955,244
Gearing, lock for, G. O. Leopold 955,815
Gearing, power, W. H. Hampton 955,818
Gearing, reversing, W. Strauk 955,717
Gearing, variable speed, F. Welker 955,488
Glove, boxing, R. Cline 955,180
Go-cart, folding, Folgeman & Kraus 955,798
Grain feeding or discharging apparatus, F. Moreau 955,606
Grass catcher, F. Wettereth 955,565 to 955,567
Grate, adjustable basket, J. F. James 955,369

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

### BUSINESS OPPORTUNITIES

WANTED. Canadian manufacturer to manufacture the Kan-get-er Sleigh-Runner can be attached to all kinds of go-carts and baby carriages, on royalty basis. For further information address Kangeter, [illegible] Pitkin Avenue Brooklyn, N Y

**Inquiry No. 9018.**—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug.

### PATENTS FOR SALE

FOR SALE.—A German patent on dough cutting and moulding machine. For further particulars address Otto Gleichter Franklin Avenue, Salem Ohio.

**Inquiry No. 9007.**—Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

### FOR SALE

FOR SALE.—Models and molds for everything in plaster iron and bronze. Ceiling outfits, drophammers and dies. Acorn Works, Indianapolis, Ind.

**Inquiry No. 9014.**—For manufacturers of machinery supplies etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

### LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co. Inc., List Department. Box 773, New York.

**Inquiry No. 9016.**—Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

### HELP WANTED.

WANTED.—A high class superintendent on track revision work raising and lowering grades. Only those with experience need apply. Experience, Box 773, N Y

### SALE AND EXCHANGE.

FOR SALE.—Engine lathe. Our regular $75.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $48.50. L. F. Grammes & Sons, Allentown, Pa.

**Inquiry No. 9021.**—Wanted to buy silk machines from re-reeling twisting doubling, to the final process of making it into clothes.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department. Box 773, New York.

**Inquiry No. 9029.**—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

**Inquiry No. 9038.**—Wanted, the address of the Chipman Electric Purifying Co.

**Inquiry No. 9042.**—Wanted the address of Furney Safety Razor Co.

**Inquiry No. 9053.**—Wanted address of firms who install plants to manufacture ultramarine.

**Inquiry No. 9055.**—Wanted address of parties interested in Log Cleaning Machines.

**Inquiry No. 9060.**—Wanted to buy machinery to manufacture seed corn racks.

**Inquiry No. 9066.**—Wanted complete outfit for export for making rice-flakes and wheat-flakes.

**Inquiry No. 9073.**—Wanted, machinery to manufacture cocoanut oil; also the crude material.

**Inquiry No. 9074.**—Wanted to buy old model locomotives or steamboats, such as were exhibited with nickel in the-slot attachments in ferry houses etc.

**Inquiry No. 9075.**—Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

**Inquiry No. 9076.**—Wanted the address of parties in Canada who could make a safety razor.

**Inquiry No. 9077.**—Wanted the address of manufacturers that make small articles of wood, such as checker boards, etc.

**Inquiry No. 9078.**—Wanted, the address of manufacturers of sewer pipe made of fiber and asphaltum, suitable for laboratory use.

**Inquiry No. 9080.**—Wanted the address of parties manufacturing paste-making machinery.

**Inquiry No. 9083.**—Wanted the address of firms manufacturing small beer brewing plants, from 15 to 100 gallons a day.

**Inquiry No. 9085.**—Wanted to buy longitudinal hollow perforated tubing.

**Inquiry No. 9086.**—Wanted, to buy a pine wood peeler.

**Inquiry No. 9090.**—Wanted manufacturers of suspender and supporters supplies, also patent adjustable bachelor buttons.

**Inquiry No. 9093.**—Wanted the address of some firms who manufacture permanent lamp wicks.

**Inquiry No. 9094.**—Wanted address of The Thomas Arithometer Company, also Burkhart Arithometer Company.

**Inquiry No. 9095.**—Wanted name and address of the manufacturer of the duplex revolving pencil sharpener.

**Inquiry No. 9096.**—Wanted the address of manufacturers of spiral welded pipes, possessing great strength.

**Inquiry No. 9097.**—Wanted address of makers of impulse water wheels.

**Inquiry No. 9098.**—Wanted name and address of the manufacturers of the [illegible].

**Inquiry No. 9099.**—Wanted address of manufacturers of machinery for making wire cables.

**Inquiry No. 9101.**—Wanted addresses of manufacturers of a dip or magnetic needle, for exploring for iron ore.

**Inquiry No. 9104.**—Wanted addresses of manufacturers under the name of A. D. Co Standard.

**Inquiry No. 9107.**—Wanted addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

**Inquiry No. 9109.**—Wanted addresses of the manufacturers of the Dion Desk Clock.

**Inquiry No. 9110.**—Wanted to buy machinery for reducing old tin cans, so that they may become a source of revenue.

# Concrete
# Reinforced Concrete
—AND—
# Concrete Building Blocks

Scientific American Supplement 1543 contains an article on Concrete by Brysson Cunningham. The article clearly describes the proper composition and mixture of concrete and gives results of elaborate tests.

Scientific American Supplement 1538 gives the proportion of gravel and sand to be used in concrete.

Scientific American Supplements 1567, 1568, 1569, 1570, and 1571 contain an elaborate discussion by Lieut. Henry J. Jones of the various systems of reinforcing concrete, concrete construction, and their applications. These articles constitute a splendid text book on the subject of reinforced concrete. Nothing better has been published.

Scientific American Supplement 997 contains an article by Spencer Newberry in which practical notes on the proper preparation of concrete are given.

Scientific American Supplements 1568 and 1569 present a helpful account of the making of concrete blocks by Spencer Newberry.

Scientific American Supplement 1534 gives a critical review of the engineering value of reinforced concrete.

Scientific American Supplements 1547 and 1548 give a resume in which the various systems of reinforced concrete construction are discussed and illustrated.

Scientific American Supplement 1564 contains an article by Lewis A. Hicks, in which the merits and defects of reinforced concrete are analyzed.

Scientific American Supplement 1551 contains the principles of reinforced concrete with some practical illustrations by Walter Loring Webb.

Scientific American Supplement 1573 contains an article by Louis H. Gibson on the principles of success in concrete block manufacture, illustrated.

Scientific American Supplement 1574 discusses steel for reinforced concrete.

Scientific American Supplements 1575, 1576, and 1577 contain a paper by Philip L. Wormley, Jr., on cement mortar and concrete, their preparation and use for farm purposes. The paper exhaustively discusses the making of mortar and concrete, depositing of concrete, facing concrete, wood forms, concrete sidewalks, details of construction of reinforced concrete posts.

Each number of the Supplement costs 10 cents.

A set of papers containing all the articles above mentioned will be mailed for $1.80.

A printed copy of the specification and drawing of any patent in the foregoing list, or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc., 361 Broadway, New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc., 361 Broadway, New York.

NOW READY

**THE SCIENTIFIC AMERICAN HANDBOOK OF TRAVEL**

**With Hints For the Ocean Voyage**

**FOR EUROPEAN TOURS**

**AND A PRACTICAL GUIDE TO LONDON AND PARIS**

By ALBERT A. HOPKINS
Editor of Scientific American Reference Book

500 PAGES 500 ILLUSTRATIONS FLEXIBLE COVER, $2.00
FULL LEATHER, $2.50, POSTPAID

AT last the ideal guide, the result of 20 years of study and travel, is completed. It is endorsed by every steamship and railroad company in Europe. To those who are not planning a trip it is equally informing. Send for illustrated circular containing one hundred questions out of 2,500 this book will answer. It is mailed free and will give some kind of an idea of the contents of this unique book, which should be in the hands of all readers of the SCIENTIFIC AMERICAN as it tells you exactly what you have wanted to know about a trip abroad and the ocean voyage.

WHAT THE BOOK CONTAINS

| | |
|---|---|
| 500 Illustrations | The Sea and Its Navigation |
| 6 Color Plates | Statistical Information |
| 9 Maps in pocket | Ocean Records |
| Names 2,500 Hotels, with price | 400 Tours, with prices |
| All About Ships | The Passion Play |
| "A Sailor Son" | Practical Guide to London |
| Automobiling in Europe | Practical Guide to Paris |

# THE ANNUAL SMALL HOUSE NUMBER *of* American Homes and Gardens

THE May Number of American Homes and Gardens is devoted to the small house, its building, its decoration, and its furnishing. This issue contains a vast amount of information for the prospective home-builder. Especial attention is given to the inexpensive and small house, which is the most numerously erected dwelling in America, and which is the type of house that at once excites the widest interest and offers the richest field for suggestive helpfulness.

Various departments conducted by specialists add greatly to the value of this number and the aim has been to bring out the charm of the simple beautiful things which contribute to domestic comfort and happiness, solely for the purpose of solving the problems that confront the house-owner but which cannot be explained without the assistance of a competent expert. It will tell him how to select a country site, how to place the house upon it, the style of architecture in which the house should be designed, how the various rooms of the house should be planned, the material of which it may be built, the kind of plumbing fixtures to be used, the choice of hangings for the walls, doors and windows, appropriate furniture for the various rooms of the house and how to lay out the grounds about the house as well as in the planting of them. Beside these departments the magazine contains a host of articles that must inevitably stimulate the desire for home improvement.

**MODERN HOUSES FROM THE ATLANTIC TO THE PACIFIC.**—This is an article by Francis Durando Nichols, treating of the modern house as seen in the various parts of the country and it is illustrated by photographic views of the exterior and interior of the houses, as well as the plans of five houses which represent the best type of modern house built at five different points.

**IDEAS FOR COLONIAL FURNISHING.**—Mary Livingston has prepared an interesting article which is illustrated by engravings giving ideas for the furnishing of the various rooms of a colonial house, beginning with the hall and passing on through the drawing-room, the library, the dining-room and to the bedrooms.

**HOME-BUILT GARDEN SEATS AND PERGOLAS.**—A. Russell Bond tells in an illustrated article how it is possible for an amateur to build a pergola and a garden seat for a small garden. The article is illustrated by photographic views showing the pergola and the garden seat and also working drawings which may be used in carrying out the subject in active detail.

**AMERICAN HOMES AND GARDENS GARDEN COMPETITION.**—The fifth prize garden won by Edward Payson, Esq., of Lexington, Mass., is illustrated by a photograph of the garden before it was developed, and also by one showing it a year later after it was developed, also a plan showing the position of the various beds of the garden.

**AUTOMOBILING.**—The automobile has become a necessity for the country house of today, and Roger B. Whitman tells in a practical way how it is possible for a man to have and maintain a modern low priced motor car. The article is illustrated showing automobiles costing from $485 to $1,000.

**THE OUT-OF-DOOR LIVING ROOM.**—The out-of-door living-room becomes a very important feature of the modern house at this season of the year, for the reason that there is no part of the house which should receive greater consideration than that of the living porch. Mr. John A. Gade has prepared an article treating upon this timely subject which is illustrated, and which shows the various ways in which a porch may be furnished and inclosed with screens in summer and glass in winter.

**SOME CALIFORNIA BUNGALOWS.**—The California bungalow is always interesting, and Helen Lukens Gaut has prepared an article on this subject accompanied by illustrations of eighteen bungalows, costing from $150 upward. The bungalow is always interesting to those who want to live out of town during the summer months, and this article tells one how it is possible to obtain a bungalow at so low a cost as $150.

**POTTERY MAKING FOR THE AMATEUR.**—Everyone is interested in pottery making, especially the kind of pottery making which can be done by the amateur. Mabel Tuke Priestman presents in a beautifully illustrated article views that show some of the most beautifully made pottery in America.

**THE SMALL KITCHEN OF TO-DAY.**—There is no part of a house which receives so little attention and yet requires so much, as that of the kitchen. Mr. Robert Spencer, Jr., has prepared an interesting article on its planning and equipment, which is well illustrated with numerous plans showing its proper relation with the other rooms of the house. All good housekeepers realize the importance of this subject, and no one is better qualified to give such information than Mr. Spencer, who has made a special study of the kitchen and its dependencies.

**THE DEVELOPMENT OF THE ARTS AND CRAFT HOUSE.**—Furnishing the arts and crafts house is a subject which is very well presented by Edith Haviland. Miss Haviland takes one through the house, and shows the proper furniture and treatment for the various rooms.

**DECORATIONS AND FURNISHINGS FOR THE HOME.**—Alice M. Kellogg presents her third paper, which is devoted to wall papers and curtains. This article is illustrated with photographic views showing the combination of wall papers and curtains of the same design and pattern for the use at windows and also for the spreads to be used upon the beds and the couch of the sleeping-room.

**THE USE OF CEMENT IN THE BUILDING OF THE SUBURBAN HOUSE AND GARAGE.**—Mr. Robert W. Gardner, the well-known architect, who has made a special study of the use of cement has prepared a very excellent article on the subject, which is profusely illustrated with many fine engravings, showing the various uses that can be made of cement in the building of the suburban house and garage.

**GARDEN NOTES, BY CHARLES DOWNING LAY.**—Charles Downing Lay describes in his department how to lay out and plant a lawn, the kind of trees and shrubs to avoid in planting and a vast amount of other information that will be helpful to those who desire to improve the grounds about their home.

**PLANNING THE SMALL GARDEN.**—The garden is a frame for the house picture and success in its treatment means that each tree and shrub should be properly placed as well as properly grown. Loring Underwood, the well-known author, tells, in a very pleasing way how it is possible to obtain this garden frame. The article is illustrated with drawings showing how the garden was planned and photographic views showing how it has been developed.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## THE AEROPLANE AND THE DIRIGIBLE

In all the history of mechanical achievement it would be difficult to find a parallel to the combination of intelligence and audacity with which a few men in as few years, have lifted the art of flying from the dreamland of the impractical enthusiast into the world of brilliant accomplishment. It was not so very long since that a scientist of world-wide reputation attempted to prove that because of certain fundamental principles the art of flight by means of heavier-than-air machines was not commercially practicable. Nevertheless within a period of considerably less than a year, more than one aviator has flown at a speed of over forty-seven miles an hour, another has covered a distance of 144 miles in a continuous flight of four and a quarter hours, a third has flown across the English Channel, and a fourth, Paulhan, the most distinguished aviator of them all, has soared nearly a mile into the air and finally has surpassed even that feat by flying from London to Manchester, covering a distance of 186 miles, with but one stop for fuel, at an average speed of over forty miles an hour.

The significance of this really wonderful race between Paulhan, the Frenchman, and White, the Englishman, is apparent only when we consider some of the details which have been cabled to this side of the Atlantic. That Paulhan should have won the $50,000 prize in such superb style at the very first trial is a tribute both to his own skill in manipulation and to the excellence of the Farman biplane with which the race was won; but to appreciate the full significance of the race, we must remember that both contestants, and particularly White, flew for a considerable stretch of the journey at night time, and what is of even more importance, that they did not hesitate to make both the ascent and the descent in the darkness. No stronger evidence than this could be afforded that the aeroplane is an instrument of precision which can be relied upon to answer with certainty to the controlling hand of the operator.

There is something strongly suggestive of bird flight in the description of the manner in which one of the contestants, after leaving the ground, swept through the air in a wide circle in order to get the lay of the land and the proper direction of flight, or to pick up again a course from which he had been driven by the wind. But certainly the most difficult feat of all was that of making a landing at night time in a locality with which the aviator was quite unacquainted, and where he had to make a wide detour looking for a suitable stretch of unobstructed surface on which to alight.

Last year, in commenting upon the status of the art of flying, we pointed out that the one last obstacle to be overcome, before flight could be reckoned among the practical achievements, was that of successful starting and alighting upon the average surface which would be encountered in cross-country flying and performing these feats with certainty in a breeze of ordinary strength. The London-to-Manchester race would certainly seem to prove that this important stage in the development of human flight has been reached and successfully passed.

In strong contrast to these achievements of the aeroplane is the series of disasters in airships, culminating in the wrecking of the huge dirigible "Zeppelin II," which have occurred during the last few weeks. Although the dirigible has proved to be perfectly stable and to possess the ability to fight its way against winds of considerable strength, the late disasters and notably the wrecking of the "Zeppelin," emphasize the fact that, whenever these huge and delicate fabrics approach, or are in contact with, the ground, they are in imminent danger of destruction. In this respect, they are in the same class as the ocean steamship, whose captain cares little what winds may blow, when once he is well clear of the land with everywhere deep water below his keel, but whose anxieties increase in proportion as the water shoals, and the vessel again approaches the coast line.

The peril of the dirigible lies in its huge bulk and the great area which it exposes to the pressure of the wind. These elements, it is true, are not a source of so much danger when once the craft is well clear of the earth and has abundance of what the navigator would call "sea room" in which to maneuver, but when it comes to the question of making a landing, and so long as the airship is upon the surface of the ground in an unprotected position, as she must needs frequently be, the dangers of disablement and even of complete disaster are ever present. We all remember how the accumulated pressure of the wind on the French airship "Patrie" tore it loose from the soldiers who were frantically endeavoring to hold it down to earth and carried it over the English Channel and across Ireland to be lost in the ocean beyond. So too in this later disaster, the "Zeppelin," during an enforced landing, was caught in an increasing wind in which it was only a question of time before the pressure proved too strong for the company of infantry that was endeavoring to hold the airship in place.

Wind pressure on large structures runs up to enormous figures. The designers of bridges make provision for a maximum pressure of thirty pounds on every square foot of surface. If we apply this unit of pressure to the "Zeppelin," we find that on a plane surface represented by the total length of 446 feet and the diameter of about 40 feet, plus the area of the cars, rudders, etc., the pressure would amount to about 250 tons, and if we admit that the effective pressure due to the circular shape of the gas bag would be only about one-half of this, there would still be a strain of 125 tons upon the guy ropes, etc., by which the machine was held in position.

If we include the Lake Constance disasters, this is the third or fourth wrecking of a Zeppelin dirigible by its being dashed to pieces in stormy weather after making a landing, and the moral is that these ships of the air should remain as far as possible permanently afloat, tying up when they wish to make a stop, to lofty steel mooring towers, which they must approach end on, and to which they must make fast by cables from the bow. This, we believe, is the plan which Zeppelin himself proposes to follow, and it would certainly seem to be the only arrangement that offers security against absolute shipwreck.

## THE DECLINE OF THE UNIVERSITY IN SCIENTIFIC RESEARCH

So many valuable discoveries and researches are now due to scientific institutions under government control or founded and supported by private munificence for specific purposes that the question arises: Is it not to such agencies rather than to the universities and colleges that we must look for the most active progress in future original scientific investigation?

Not only are these institutions for special research freed from the duty and cares of teaching, but what is of greater importance, their organization and equipment are generally far more efficient. Every possible assistance is rendered to the individual investigator, and he in turn is carefully selected for his proficiency and promise, and with ample facilities at his disposal and supplied with an adequate salary, he is expected to work systematically along certain definite lines with entire freedom from financial or administrative concern.

At the head of these institutions there are usually directors who are men not only of eminence in their special science, but competent to organize and conduct campaigns of scientific research, which may include a number of workers often in widely different fields, yet all engaged in studies merging into one definite scheme. Each worker receives full credit for his particular contribution, and the solution of great and complex problems is undertaken with all the efficiency of organization and co-operation characteristic of the best and most modern industrial and commercial practice. Yet there is no sacrifice of the true scientific spirit and the only elements of the commercial world that are applied are economy of effort and resource, efficiency of organization, and adequate capital and plant to push to a satisfactory outcome any particular project or class of investigation.

These conditions have attracted many investigators of reputation, and in such scientific establishments as the various laboratories of the Carnegie Institution of Washington, the Rockefeller Institute for Medical Research, and the research laboratories of manufacturers' associations and large corporations, not to mention those conduc[illegible] auspices, much scientific work [illegible] is done. One might refer t[illegible] for the study of tuberculosis [illegible] diseases, to national physical [illegible] and bureaus of weights and [illegible], to astronomical observatories and biolog[illegible] museums and meteorological observatories. In nearly every case there would be fo[illegible] record of scientific activity. This work is of an original character and is often important both to science and in its application to the everyday affairs of humanity.

With this ever increasing efficiency on the part of special research institutions, we are brought face to face with the fact that no longer are American colleges and universities with their various scientific schools and laboratories in as good a position to forward scientific research as of old. In a few cases there are special endowments which support observatories, laboratories or clinics where there is but slight interference from governing boards and administrations, but, speaking generally, the American university is not always able to supply the material facilities for modern research, nor is its organization such as to make its prosecution possible under conditions of economic efficiency. For so extended is the work of the great American university that its departments cover at least in theory, an inconceivably wide range of knowledge and [illegible], and for their support appropriations none [illegible] must be granted by administrations and governing boards without any exact and special knowledge of their comparative needs or the merits of [illegible] work. Where even the lay trustees of a special institution can pass understandingly on the plans, projects and budgets of such an organization, with [illegible] defined field the governors of a university, overwhelmed by the intricacy of the situation as well as by the magnitude usually adopt a policy of averaging their appropriations to different departments rather than of assuming the responsibility of passing on the merits or urgency of their work.

But important as are material support and facilities to modern research, this is by no means the only or most serious question for the man of genius triumphs eventually over the difficulties due to their absence. So extended have American universities recently become, both in scope and number of students, that members of their faculties are compelled not merely to give an unduly large amount of instruction along lines once considered fundamental, but in addition to offer courses in special or allied branches involving no small amount of painstaking preparation. So keen is the competition on the intellectual side and in the number of courses offered and in the desire for large registration that an executive head of the university demands from his staff as a condition of salary advance or promotion, the greatest possible amount of teaching, be it congenial or not. Under such conditions it is not difficult to see that the time and inclination for special investigation and research by a young scientist occupying a university chair may be seriously curtailed. Furthermore, so intricate is modern university mechanism and even minor administration that from a professor there is required an ever-increasing amount of clerical labor in the compiling of statistics and other records, and information about students and departmental activities, according to the exactions of the educational machinery, which to-day is apt to imitate commercial forms rather than commercial efficiency and economy of effort. Thus in the misunderstanding of the professor's function and misuse of his time, a partial explanation may be found for the [illegible]tively poor showing that American professors of science make in comparison with their European colleagues. This condition, university presidents and trustees in America tell us, can be remedied by the provision of great and further endowments for research chairs and laboratories, but it now seems an open question whether such funds are not more productive when applied to special institutions apart from educational machinery. It must not be understood that the training of young men for scientific research has experienced any slackening of effort in our universities and technical schools for it is these men stimulated as never before by their professors, who will bear forward the torch of scientific progress. Education and original discovery seem destined in the future to be carried on by totally distinct organizations.

---

That the silver area in northern Ontario is continually being widened is evidenced by the discovery of native metal about fifty miles west of Cochrane, on the Grand Trunk Pacific. It is understood that the discovery was made in blasting out a railway cut. When the news reached Cochrane, sixty prospectors started out the next morning and this number is being constantly augmented by fresh arrivals.

## AERONAUTICS.

**Mr. A. L. Pfitzner** has been making successful flights with his novel monoplane (which was illustrated in our issue of February 12th) of late in various places On April 15th he made three successful short flights at the Buffalo Country Club, and in the fourth flight he ran across the field at a high rate of speed, rising to a height of ten or twelve feet, when a gust of wind struck the machine and drove it to the ground with great force. The aviator was bruised and badly shaken up, and his machine was more or less seriously damaged. Despite his accident, Mr Pfitzner has demonstrated that his novel sliding wing tips work well

**Messrs. A. M. Herring** and W S Burgess have been experimenting with the former's new biplane on Plum Island, opposite Newburyport, Mass. This new machine, which was illustrated in our issue of March 19th, has demonstrated that it can glide over the ground and rise from its single skid without the use of wheels. On April 17th, Mr Herring made a short flight of about 250 yards On the 21st he made three other flights, in the longest of which he covered about 300 yards at a height of fifteen feet The next day Mr. Greeley S Curtis, while flying the machine at an estimated height of thirty feet, lost control of it The biplane descended and struck the ground head on, fortunately in a soft meadow It was badly smashed, but the aviator was not injured

**While aviation** advances by leaps and bounds, aerostation has had several serious setbacks of late To begin with, on April 3rd the German balloon "Pommern," celebrated for having won the Bennett cup race in America in 1908, fell into the Baltic Sea and three of its four occupants—one, Herr Delbrück, a member of the Reichstag—were drowned The next day, Prof Abegg, a well-known German chemist, was killed while making a landing, while on the 18th ultimo the balloon "Delitzsch" carrying four men burst during a thunder storm while at a height of several thousand feet, all its occupants being killed by the fall. It was at first supposed that the balloon was struck by lightning, but this was afterward found not to be the case Emperor William, however, has had a thorough investigation made and is getting together all the facts regarding the igniting of the gas in balloons by atmospheric electricity

**As far as dirigible balloons** are concerned, Germany, which for some time past has been in the lead with this form of air craft, has also suffered severely After making various cruises in the vicinity of Cologne, the "Zeppelin II" "Gross II," and "Parseval I" airships flew from that city to Homburg on April 22nd and were reviewed by Emperor William As a gale sprang up, the airships were moored at Homburg over night. As strong winds continued, the "Gross II" (which is a non rigid dirigible) was deflated and shipped back by rail. The "Parseval" and "Zeppelin II" attempted to make the return journey, but only the former was successful in accomplishing it. The "Zeppelin" lost gas and was forced to descend at Limburg, where it was moored again over night, and fully inflated in the morning At noon a sudden squall of wind tore the huge dirigible from its moorings and it floated off without a crew A half hour later it was driven to the ground at Weilburg It fell beside a cliff and broke in two The sudden demolishment of this, the principal airship of the German fleet, has shown how precarious is the existence of these leviathans of the air

**On April 21st** Prof John J Montgomery, of Santa Clara College, Santa Clara, Cal, lectured before the Aeronautical Society in New York upon his aeroplane experiments. These were begun in 1883, and Prof Montgomery met with no little success from the start After first trying a flapping-wing machine, he next built a monoplane glider having wings 10 by 4½ feet in size, and patterned after the wings of a gull, i e, with a downward curve in front. Upon running down hill with this first glider, he rose and glided 600 yards He steered and maintained equilibrium by leaning his body to one side or the other He next endeavored to secure better control, and to this end studied the birds closely He was able to determine just how they warp their wings. Then he built several machines with warpable wings resembling a fly's wing in structure He made scientific experiments upon the lifting power of curved surfaces; and he finally evolved a Langley-type warpable glider having curved surfaces and a *fixed vertical* tail (in conjunction with a movable horizontal tail) that worked splendidly, and that could be steered simply by warping the wings. This machine, piloted by Daniel Maloney, was cut loose from a balloon at heights of 1,000 to 3,000 feet, and the aviator was able to pick a landing place and alight wherever he pleased. Prof Montgomery secured a U. S. patent (No. 831,173) on September 18th, 1906, and in view of his practical demonstration of steering *without the use of a vertical rudder*, it would seem that this rudder is not as essential as the Wright brothers claim.

## ELECTRICITY

**The Subway** Telephone Construction Company of Chicago has promised to provide that city with a complete automatic telephone system by the first of June next year At first it will cover only the business district, but later will be extended to the residential sections

**Merchants** in the South have awakened to the value of rural telephone lines, and are seeking to develop them, with a view to increasing their trade among the rural population In certain sections they have made large contributions to aid the farmers in building their lines

**The Weather Bureau** has arranged to give daily weather forecasts by telephone to farmers in Texas At noon each day rural subscribers are called up, and the weather forecast is announced to all simultaneously Subscribers in towns and cities can obtain the weather forecast at any time of the day after 11 A. M by calling up central

**A writer** in Physikalische Zeitschrift has been investigating the frequency of electrical oscillations when a condenser is discharged through a spark gap He finds that this depends to a large extent on the nature of the electrodes. For instance, a discharge between copper and silver electrodes would give a longer wave length than a spark between magnesium electrodes, and he comes to the conclusion that magnesium is the most suitable metal for spark electrodes

**A new** system of jointing lead cables has been developed in England It consists in placing a thin ribbon of pure tin between the surfaces that are to be joined, and then heating them with a blow lamp. The surfaces in the presence of the tin melt at a lower temperature than normal, and thus they are soldered together The tin ribbon is treated with a composition to prevent oxidation during heating Another system of jointing consists in the application of a mold over the cable A piece of tin ribbon is applied to the surfaces which are to be joined, and then molten lead is poured into the mold The flow is so directed as not to burn through the lead sheathing of the cable

**The fourteen-year-old** president of the Junior Wireless Club of America appeared before the Senate Committee on Commerce last week to protest against the bill introduced by Senator Depew for regulating wireless telegraphy The young president gave a very forcible argument in favor of amateur wireless telegraph operators, pointing out the fact that if the bill were passed it would check the inventive genius of some forty thousand experimenters He also called attention to the fact that it would be impossible to enforce the bill without a veritable army of expert wireless telegraph engineers The junior wireless telegraphers claim that it is possible to cut out interference if the proper apparatus is used, and that the present attack on amateur wireless telegraphers is unwarranted

**The Third Avenue Railroad Company** of New York tried out last winter a gasoline-electric car on its crosstown lines. Now another type of car is being tried, and a comparison will be made of the two The new car is a reconstructed horse car provided with Gould storage batteries and a pair of five horsepower motors The battery is placed under the seats of the car and has a rating of 420 ampere-hours at 84 volts It is made up of twenty-nine plates per cell, and there are forty-four cells at each side of the car The gases that are generated by the battery are carried off by a ventilating system and exhaust under the rear platform The car weighs only six tons fully loaded It has been found to consume in actual service only 0.54 watt hour per ton mile, while maintaining a speed of six miles per hour with nine stops per mile

**The steel hull** of a vessel is rendered magnetic during construction by the hammering of the metal, and every steel vessel has to have its compass corrected to counteract its own magnetic lines of force The magnetic influence is further complicated by the load carried by the vessel if this load is magnetic or capable of being magnetized The ore-carrying vessels of the Great Lakes experience great difficulty on this account, and the United States Hydrographic Bureau is endeavoring to teach pilots and captains of vessels plying in this trade how to check their course by means of the pelorus The pelorus is an instrument similar to the sun dial, being provided with a gnomon and a graduated arc on which a shadow of the gnomon is cast. The instrument is set in a north and south direction, as indicated by the compass, and then by noting the shadow on the graduated arc, it is possible to tell by comparison with tables, furnished by the government, just how far from the north and south position the gnomon really lies, thus showing the compass error

## SCIENCE.

**Prof. Adams,** of the Mount Wilson Observatory, has been making a spectroscopic study of Halley's comet He finds the head to be surrounded by cyanogen gas and the tail to be composed of hydrocarbons

**Sir Ernest Shackelton** received a gold medal from the Geographical Society of Philadelphia at a dinner given in his honor on April 22nd Among those who spoke in praise of Sir Ernest's achievements were such famous Arctic explorers as Rear Admiral George Melville and Amos S Bonsal

**In an article** published in Light Mr Robert E Livingston states that the first man to use gas in New York city was Mr Samuel Legget who lighted his house at No 7 Cherry Street with it The people kept at a respectful distance from the house, fearing an explosion Newport Rhode Island, and Baltimore Md, soon followed New York

**Rev. George M. Zwack, S. J.,** secretary of the Philippine Weather Bureau has prepared at the request of the insular government a paper on "The Return of Halley's Comet and Popular Apprehensions" for distribution throughout the islands with the object of reassuring the natives, who, it is said, are already a prey to many wild rumors on this subject

**The American Philosophical Society** of Philadelphia has decided to assist in the movement for an expedition for south pole exploration The project was urged in 1909, when the following scientific societies united in an appeal to Congress The American Academy of Arts and Sciences American Geographical Society California Academy of Sciences, New York Academy of Sciences, Franklin Institute, Geographical Society of Philadelphia, American Museum of Natural Sciences, Geological Society of America Association of American Geographers and the American Alpine Club

**In a lecture** delivered before the Royal Society of Naples Prof A Piutti called attention to the discovery by Palmieri in 1881 of a characteristic line of helium in the flame spectrum obtained by heating in a flame "an amorphous, buttery substance of a yellow color which was found as a sublimate on the edge of a fumarole near the mouth of Vesuvius" This is generally accepted as the first discovery of terrestrial helium, although Nasini and Andelini in 1906, on examining the flame spectrum of a large number of volcanic incrustations failed to recognize the presence of helium in any of the specimens they examined under the condition described by Palmieri

**The Express** of London claims that another word must be added to the dictionary of gardening This is "Caloriculture" the name of an entirely new system of horticulture which has recently been inaugurated, and bids fair not only to replace the form of intensive culture of the French school, but to revolutionize the present system of fruit and vegetable forcing While it is nearly customary to look for extreme and favorable developments in the line of soil cultivation, through French means, to us in the United States, who have not the garden habit quite so strongly as obtains in France it comes as a surprise that the inventor of the new method is a Briton Dr F Alexander Barton, Fellow of the Royal Society

**For the last year** systematic excavations have been made at Ostia, the ancient harbor of Rome at the mouth of the Tiber The ruins of a large city built probably by Hadrian over the old republican town, have been uncovered Archæologists consider the discoveries as important as those of Pompeii Heretofore it has been believed that Ostia was founded by Ancus Martius the fourth King of Rome that it was destroyed by Marius during the civil wars rebuilt during the republic sank into insignificance, and was buried in the sand and deposited in the Tiber when Trajan built the new port and city of Portus Instead of this it is now certain that Ostia not only continued to flourish under Hadrian but that the old level was raised six feet and that the republican town served as the foundation for a model city with rectangular wide streets, temples fora and squares

**A case** of extraordinary if not unprecedented horizontal temperature gradient is reported on apparently trustworthy authority in the Meteorologische Zeitschrift for March 1910 With a temperature ranging between 0 deg and +2 deg C at Helsingfors Finland on November 18th, 1909 a temperature of 20 deg to 24 deg C was simultaneously recorded at a point only 10 kilometers distant to the north, a difference of about 20 deg C (68 deg F) in a distance of about 6 miles While the climate at Helsingfors is tempered by the Gulf of Finland so remarkable a difference between the temperature there and in the immediate hinterland is inexplicable especially as the two stations at which observations were made are of the same altitude The strangest part of the story, however remains to be told viz., that a little to the north of the place where the low temperature was reported the weather was almost as warm as in Helsingfors"

# THE NICE AVIATION MEET

## WITH DETAILS OF THE CROSS-COUNTRY RACE FOR THE LONDON DAILY MAIL'S $50,000 PRIZE

One of the principal aviating meetings which has been held abroad this year was that at Nice from April 15th to 25th. Two of our illustrations show Farman biplanes that participated in this meeting. The one in flight over the sea was piloted by Duray, an old-time automobile racing driver, while the one which is shown on the beach was piloted by George Chavez. Chavez on the 17th ultimo accomplished several long flights above the sea. In one of these the fuel gave out and the machine landed on the beach, as shown. The meet opened under auspicious weather conditions, and some splendid flights were made on the opening day. At one time in the afternoon four biplanes and a Blériot monoplane were all in the air at the same time. Effimoff, Chavez and Van den Born, all of whom flew Farman biplanes, made some excellent flights. Rougier also made brilliant flights, on one occasion crossing the Var, and another time flying half a mile out to sea. Metrot flew for half an hour on his Voisin biplane, and Olieslagers made several short flights in his Blériot monoplane, which appeared to interest the spectators more than the biplanes on account of its bird-like appearance. The English entrants in this meet, Messrs. Rawlinson and Rolls, were unfortunate. The first named was unable to fly more than half way around the track the first day on account of trouble with his Darracq motor, which he was using on his Henry Farman biplane, while Mr. Rolls did not receive his Wright biplane from England.

The second day of the meet nearly all the aviators made excellent flights. Herr Grade's monoplane failed to arrive, and so he did not participate in the flights. Effimoff made a flight of 80¾ miles, and Van den Born flew 40 miles. Mr. Rawlinson made a daring flight out to sea. While turning above the water, he was approached too closely by Effimoff, the result being that although the two aeroplanes did not touch each other, Mr. Rawlinson's fell into the sea, and was badly damaged. The Russian aviator was fined for faulty driving.

The results of the first day's flights in the various contests were as follows:

*Total Distance Prize*.—Effimoff (Farman biplane), 130.716 kilometers (81.17 miles); Chavez (Farman biplane), 105.508 kilometers (65.52 miles); Van den Born (Farman biplane), 87.508 kilometers (54.34 miles); Metrot (Voisin biplane), 15 kilometers (9.31 miles).

This competition was for the total distances flown in all flights made during the day by each competitor.

*Starting Prize, Without Passenger*.—Effimoff (Farman biplane), 80 meters (262.4 feet).

*Starting Prize, With Passenger*.—Effimoff, with Prince Koudacheff (175½ pounds), 100 meters (328 feet).

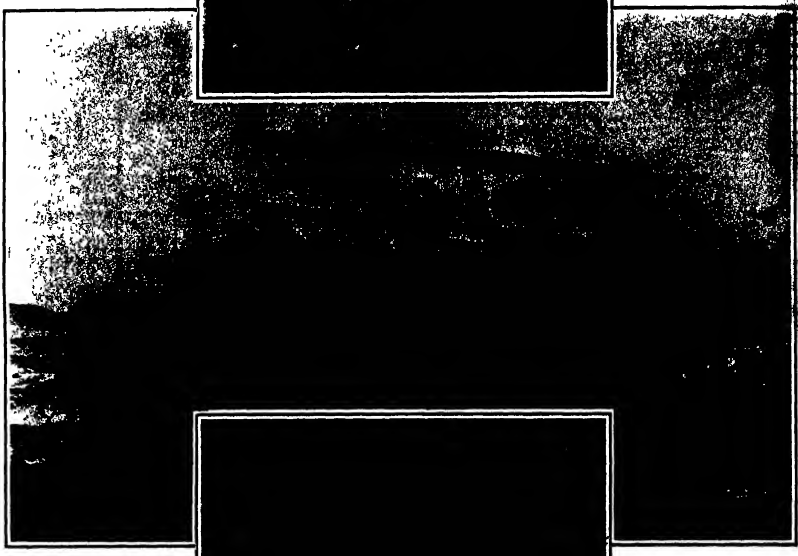
Prize for fastest circuit of the course, $400. Won by Effimoff, who flew 6 kilometers (3.73 miles) in 6 minutes 23 3/5 seconds—a rate of 35 miles an hour.

In this aviation meet over a dozen aviators competed, and many other flights were made.

The greatest sporting event that aviation has had thus far, as well as the chief demonstration of the practicability of the aeroplane for the rapid transportation of individuals, was the race from London to Manchester, England, on the 27th and 28th ultimo, for the prize of $50,000 offered three years ago by the London Daily Mail. On April 23rd Mr. Claude Grahame White, an Englishman, attempted the flight on his Farman biplane. After covering the 115 miles to Litchfield in 3 hours and 6 minutes, he quit battling with the violent wind and the cold. The next day his aeroplane was badly damaged by the wind while in its temporary shelter. It was taken apart and shipped back to London for repairs. Meanwhile aviator Louis Paulhan visited London and entered the race. His Farman biplane arrived from France on April 27th, and after working hard all day at Hendon, he got it assembled and started aloft at 5:21 P. M., flying immediately to Hampstead (5 miles from London) and crossing the starting line at 5:31. He had a map tied to his waist, and he [illegible] a special train on the railway 1,000 feet below.

Soon after Paulhan started, word was brought to White, who had completed the repairs to his machine and who was resting at his hotel. Rushing in an automobile to his aeroplane, he started at 6:23 from Wormwood Scrubbs in pursuit of Paulhan. But the latter had gained an hour's flying time before darkness settled down, and he alighted at Litchfield at 8:10 just as the 14 gallons of gasoline he carried were entirely consumed. White alighted at Roade, near Northampton, after a flight of 1 hour and 23 minutes in which he covered 60 miles. He started again at 2:54 A. M. and succeeded in getting within about 15 miles of Litchfield before Paulhan again resumed his journey. He flew over Weedon, Crick, and Rugby in the darkness, and alighted at Polesworth, nearly 100 miles from London, after an hour's flight. Late in the afternoon he flew 10 to 12 miles farther, but the race practically ended for him at Polesworth. The conditions required the flight to be made within 24 hours and with not more than two stops en route. Paulhan

(Concluded on page 38[illegible].)



1. Chavez's wrecked Farman machine which dropped into the water when his fuel gave out. 2. Duray flying over the breakers in his Farman biplane. 3. A novel hydro-aeroplane fitted with a three-cylinder Anzani motor.

THE AVIATION MEET AT NICE.

## PECULIAR SPIRAL ARCH OF THE ESKIMO SNOW HOUSE.

BY A. L. KROEBER, CURATOR OF ANTHROPOLOGY, UNIVERSITY OF CALIFORNIA

There is a type of dome that can be built without a scaffolding and that requires a man to be immured within the vault to insure proper construction. It is the invention and sole property of that most ingenious of savage races, the Eskimo and contains several principles new to civilized architecture.

There are four fundamental types of arch and dome, of which one is the Eskimo peculiarity. The simplest and least used, because least effective is of the simple lean-to type—illustrated by and to-day chiefly employed for, the house of cards. Next comes the false inverted-step arch where each block or brick projects beyond the one below and is held from toppling in by the weight of the material above and behind it. This type of gateway and chamber was invented independently by the architects of Agamemnon more than 3,000 years ago in ancient Greece and the precursors of the Aztecs in Mexico at nearly as early a period. This construction inherently demands a vast amount of backing or fill in proportion to the vault of the arch. It is feasible for a gate in a long wall, or for an underground hall or drain but cannot stand alone and is a *false arch*. A free portal, or a dome rising into the air cannot be built on this principle which is consequently but little employed to-day. Our true arch embodies the third method its essential feature being the use of wedge-shaped blocks. When the last and central one of these pieces—the key stone—is dropped into place the whole mass supports itself. The top cannot fall inward unless the supports are toppled outward. The primary thrust is therefore always not in but out and buttressing of some sort is requisite. Another inherent defect of this arch though we are so accustomed to it that we do not usually note the fact is that until the key stone is fitted into final position a temporary structure must be erected to hold up the parts already in place. The last type the Eskimo vault is a true dome exerts no outward thrust and requires no temporary scaffolding. It is also unique in that its material is not brick or stone but *snow*.

The construction is used for the beehive-shaped winter houses of these so-called savages and is spiral in plan as shown by the diagrams. A row of blocks is first laid on the ground in a circle—or more exactly a polygon. Each of these has a slightly slant top and each thus raises its surface a little beyond the last until when the circle is completed the gap in height between the last and first blocks gives the thickness for the following courses. In these the upper and lower surfaces of each block are parallel as in a brick but the gradual upward trend given by the first course is of necessity maintained.

In each successive round the snow bricks are leaned inward more by having their lower surfaces sliced off to a bevel. If set squarely end to end they would before long lean inward so far that they would tumble. For this reason the end of the block last laid is cut at an angle. The next following block has the joining end slanted at the reverse angle. Thus it fits in behind the preceding and is prevented by it from slipping inward. As the house grows the circles become smaller until at last only an irregular polygonal opening is left. This is filled with a wedge-shaped block cut to shape. It is however not a key stone as the remainder of the structure supports itself.

The blocks of firm snow are usually dressed outside and handed for placing to the man on the inside. The last block he holds up with one hand slices to shape with his ivory knife in the other, and drops into position. He is then entirely inclosed in the vault. Only after the house itself is entirely completed does he cut out the low door, which to keep out the cold as much as possible is only big enough to crawl through. A long low tunnel is then built in front of the door, to break the force of the Arctic's icy blasts. Even a window is present. A small aperture is cut out over the door and filled with a pane of clear thin ice. All that is omitted is the flue or chimney. Whatever heat is produced by the seal-oil lamps is wanted inside, warmth being a more serious necessity in the climate than ventilation or freedom from smoke.

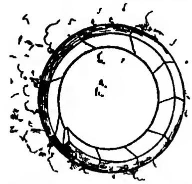
Whether the type is practicable in other materials has been doubted. The unsurpassed lightness of snow is certainly a great advantage. In heavier materials strength would, however, compensate for increased stress of gravity, and good mortar should make up for the inward slipping tendency that weightier materials would show.

The greatest difficulty in working in stone would be encountered in shaping the separate pieces of masonry. Owing to the spiral and leaning construction no two blocks can be exactly alike in either shape or size and in every succeeding course each block departs more and more from the right angle in its proportions. To compute in advance exactly the proper angles for each piece so as to insure true joints would be a matter of much complex mathematical calculation.

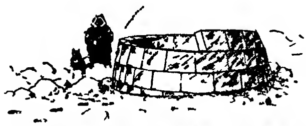
It might however be practicable once the calculations had been determined for a building of standard size to draw up a table of the angles and dimensions required for each successive block. If the size of the structure were reduced or increased from the standard each stone would only require to be diminished or enlarged by a fixed ratio.

It would take our ablest engineers longer to plan such a dome than an Eskimo would need to build a village but the resulting simplicity of construction due to the inevitableness and simplicity of the progress of erection without any temporary supports but tresses or reinforcement might more than compensate.

The spirally ascending bevel locking Eskimo dome is the only true vault any part or the whole of which will stand entirely by itself.



**Plan view of partly built hut, showing how each block supports the next.**



**Eskimo hut partly built. The snow blocks are laid in a continuous spiral course.**

**Section through Eskimo snow house.**

THE PECULIAR SPIRAL ARCH OF THE ESKIMO SNOW HOUSE.

## A GASOLINE MOTOR DRIVEN EARTH-BORING MACHINE.

BY WALTER LAN FORD

The details of construction and method of operation of a unique gasoline motor-driven earth boring machine are shown in the accompanying illustration. The device was recently designed in California by Charles I. Belty and the photograph represents it in working position in actual operation at Sacramento and near Selma, Cal.

It is stated that with one of these machines about 25 miles of holes were bored for use in fencing along the right-of-way of the Western Pacific Railroad between Marysville and Oroville, Cal. These holes were bored under particularly trying conditions as the ground was gumbo land with the exception of a short stretch of marsh soil and so hard and so dry that every bit of it had to be broken with pick and crowbar when dug by hand. Part of it in addition to the hard ground had about 20 to 25 per cent small cobble yet this labor saving device bored through all of it and did the work of from twelve to fifteen men.

Such a machine is of great value for boring holes for posts for numerous other uses for which shallow holes are required and for the purpose of lightening the labors of man. Experience shows that the harder the ground and the more difficult it is to work the more earnestly a machine of this class is desired.

This entirely new unique and practical engine driven apparatus is a most remarkable device in its simplicity and owing to its wide range of uses as a labor saver it stands unsurpassed. It will be seen that it is extremely simple easily operated and entirely practical and will be found a great economizer of time and money where post holes are to be dug electric line telegraph or telephone poles set or where trees and vines are to be planted in holes uniform in size at top and bottom and of suitable diameter and depth.

It is held to be practical for use everywhere as by it the machine will work satisfactorily in either dry or wet soil or in any place where the machine can be driven as it bores readily through hardpan and shale soft sandstone and small cobble and as it will bore at different angles and on either side or back of the truck it will do equally good work whether on level ground uneven ground or hillside.

Near Reedley, Cal., a great number of holes were bored in very hard hardpan for large poles the machine being particularly successful in this work because the contrast between its efficiency and hand labor was so strongly marked. At Mendota, Cal., a record was made by one of these machines on large fence work in hard dry earth 90 holes being bored 33 feet apart and 30 inches deep in 60 consecutive minutes the holes being 8 inches in diameter.

For use in boring small holes a vertical engine of the double cylinder type is utilized that develops 7½ horse power. In boring holes for large poles a machine of this type is fitted with an 18 inch auger effecting a depth of 6¼ feet. The power is supplied in this case by a double cylinder gas line engine of 12 horse-power capacity.

This device is said to be inexpensive to operate as a man and a boy only are required for its efficient working the boy to drive the team and the man to manage the machine. Its not earning capacity is said to be greater than that of a threshing machine costing five times as much. Its season of usefulness extends over the entire year and in many instances in hard ground has done the work of fifteen men.

It is maintained that in cold countries where other farm work

WORKING POSITION OF EARTH-BORING MACHINE READY TO BORE A HOLE.

is impractical during the severe season, post holes can be dug and fences built during the winter, as this machine is well adapted to boring through ice, frozen ground, hardpan, shale and the like

In the planting of orange trees peach trees, grape vines or in having a piece of land underlaid with hard pan in which holes for any purpose are expensive to dig this form of machine will do the work of making an opening through any crust for the top root of the tree

The upper frame and boring tower being on a rotatable platform, one can easily adjust the machine to a hole on either side or at the rear of the machine When the device is in a position to bore a hole, all that it is necessary to do is to pull the feed clutch, and the auger drops to the ground and begins work, when the auger is loaded, by releasing the feed clutch and pulling the hoist clutch in, the auger is hoisted clear of the ground, or to any other position that may be desired

It is of interest to note that besides boring in the kinds of soil before mentioned the machine will bore in dry clay, or in swamp land without any change of augers or bits no ground being too sticky for it to work There is no necessity of stopping the machine to clean mud off the auger as the machine does that itself

If there is an occasion to bore a line of holes down the middle of a well traveled road it will do the work without difficulty A small type of earth boring machine has been designed which will bore to a depth of 4 feet and which is equipped with two augers 8 and 12 inches in diameter, while a larger machine has been developed which will hole to a depth of 6 feet The latter is fitted with three augers 8, 12, and 16 inches in diameter

It is stated that no change of shaft or auger is required to make the depth indicated The time required to move from one hole to another and begin work in a fence line is from 15 to 25 seconds

The feed pinion of the machine as well as the feed rack, drill shaft gearing, and auger shaft are made of crucible and machinery steel so as to withstand a sudden impact as when stopped by running against rocks, old posts and similar obstacles

Chain belting is used of the standard sprocket type and in case of a break can be easily replaced It will be seen that this machine in boring does not scrape the earth but cuts it with chisel bits, which are quickly detachable the entire set being changed in two minutes if desired

It is reported that this machine has bored many holes 30 inches deep in hard ground in fifteen seconds for each hole from the time the auger touches the ground, and it is hard ground indeed when the hole cannot be bored in a minute It has force feed, and therefore all the attendant has to do is to pull the lever and the machine does the work

## LAUNCH OF THE "FLORIDA."

On the morning of Thursday, May 12th, there will be launched at the Brooklyn Navy Yard the second of the two largest battleships yet built in the United States the "Florida" The sister ship, the "Utah," which in December last took the water at Camden N J from the building slips of the New York Shipbuilding Company, weighed about eight thousand tons The launching weight of the "Florida" will be about nine thousand tons, which is, in itself a record for an event of this character The keel of the "Florida" was laid on March 9th of last year, and the work of construction has been carried on uninterruptedly under the supervision of Naval Constructor William J Baxter with Naval Constructor William G Groesbeck immediately in charge

In view of the great importance of the ship, and the gratifying rapidity with which she has been built, preparations have been made to render the ceremony of launching particularly brilliant Among the guests on the launching platforms will be President Taft, Secretary George Von L Meyer, Assistant Secretary Beekman Winthrop Albert W Gilchrist Governor of Florida with his staff, Admiral Dewey, and Rear Admirals Evans Sperry Schroeder, Wainwright, Potter and Lucien As the battleship fleet is now present at the yard between six and seven thousand bluejackets and the officers of the ships will assist in giving dignity to the event In agreement with the custom of having our ships christened by a representative of the State or city after which they are named, the ceremony will be performed by Miss Elizabeth Fleming of Jacksonville Fla

The naval constructors and employes of the Brooklyn Navy Yard are to be congratulated on having, for the second time demonstrated that they are capable of building the largest and most modern warships, not only with dispatch but of the most thorough and durable workmanship, for it will be called to mind that from these very ways there was launched on September 29th 1904 the flagship "Connecticut," which, although a much smaller ship than the "Florida" (less by about 6,000 tons, in fact) was nevertheless the largest vessel of her time in the United States navy, and approximately as large as any vessel in the navies of the world. It is a long step, however, from a 16,000-ton "Connecticut" to a 21 825-ton "Florida," and the Brooklyn Navy Yard should receive full credit for the fact, that while eighteen and a half months elapsed from the laying of the keel to the launching of the "Connecticut," it has taken only fourteen months to do the same amount of work on the big ship The material has been built into the hull at an average rate of about twenty-five tons per working day of eight hours If all goes well, the hull and accessories will be completed early next spring. The date of the completion of the machinery is somewhat uncertain, the recent reorganization of the navy yard having thrown the steam engineering shops somewhat out of their stride

The greater length of the "Florida," which exceeds the "Connecticut" by over sixty five feet, her greater beam of eleven feet four and a half inches, and her increased launching weight of many thousand tons necessitated, of course, a great enlargement and strengthening of the permanent and launching ways, and severely taxed the capacity of the building slip Our front page illustration shows how the ram of the ship extends entirely across one of the streets of the yard and abuts against the wall of a building

In spite of this fact, the stern of the vessel reaches almost to the bulkhead wall on the water front

Just here it is well to notice how, in order to secure the desired speed of 20 75 knots, the lines of the ship have been fined out, as compared with former battleships The entrance of the "Florida" appears to be as fine as that of our armored cruisers At the same time in order to secure good lifting power forward, when the ship is driving into head seas, above the water line the sections are flared out very rapidly, thus giving the ship a form which is not only buoyant and seaworthy, but adds greatly to the appearance of the vessel

The "ways" consist of the permanent ways made up of the supporting piling, cross caps and longitudinal timbers and the launching ways, in which she immediately rests, built to conform to the underwater form of the ship, which travel with her as she moves down into the water The heavy longitudinal timbers, which form the sliding surfaces between the fixed and launching ways, are thoroughly lubricated with a special preparation, consisting chiefly of tallow, lard oil and graphite The contact surfaces are made sufficiently broad to bring down the maximum pressure on the ways to 2 2 tons on each square foot The ship is released and started on her swift slide into the water by sawing through the "sole beams," which are the last members that connect the launching ways with the permanent ways The "Florida" will move very slowly at first but gather way rapidly, and her highest velocity will be about twenty miles an hour

With the launching of the "Florida," the United States navy will have afloat its first complete division of ships of the dreadnought type consisting of the "Delaware," "North Dakota," "Utah," and "Florida." A study of the accompanying table shows that the

COMPARISON OF THE "NORTH DAKOTA" 1908, AND THE "FLORIDA," 1910.

| | "North Dakota" | "Florida." |
| --- | --- | --- |
| Length | 518 feet 9 inches. | 521 feet 6 inches. |
| Beam | 85 feet 2½ inches. | 88 feet 2½ inches |
| Draft, mean | 26 feet 11 inches * | 28 feet 6 inches.† |
| Displacement | 20,000 tons. | 21,825 tons. |
| Coal supply | 2,500 tons | 2,500 tons. |
| Oil | 400 tons. | 400 tons. |
| Belt armor | 12 inches to 8 inches | 11 inches to 8 inches |
| Turret armor | 12 inches. | 12 inches. |
| Battery armor | 8 inches | 6½ inches. |
| Smokestack protection | 6 inches. | 9½ inches. |
| Twelve inch guns | Ten | Ten |
| Five inch guns. | Fourteen | Sixteen |
| Speed contract | 21 knots. | 20.75 knots. |

* With two-thirds full supply ammunition and stores

† With two-thirds full supply stores and fuel and full supply ammunition

"Florida" is an enlarged "North Dakota," having the same length between perpendiculars, and two or three feet greater length over all, three inches more beam; one foot seven inches more draft, and 1,825 tons greater displacement She is designed to have three thousand more horse-power, but a quarter of a knot less speed The armament in each case consists of ten 45-caliber 12-inch guns mounted in five turrets on the center line of the ship The 12-inch pieces for the later ships in the case of the "Wyoming" class will be more powerful, being fifty calibers in length with a correspondingly greater muzzle velocity and energy In the broadside, torpedo-repelling battery, the "Florida" has two more 5-inch guns than the "North Dakota."

It is claimed by our Navy Department that the "Florida" and her sister are the best-protected warships afloat special attention having been given in her design to guarding the vital parts of the ship against mortal injury and to the localizing of the destructive effects of projectiles and torpedoes. Against sinking by torpedo attack the "Florida" is safeguarded by an elaborate sub-division of the hull and an unusually powerful pumping plant for ridding the ship of such water as may enter Against gun fire she presents probably a more complete system of armor protection than any contemporaneous warship. The main armor belt, over eight feet wide, has an average thickness of eleven inches, above this is another eight-foot belt averaging nine inches thick, while the five-inch broadside battery on the main deck and the bases of the smokestack carry heavier armor than has been placed on any previous United States ship, the front wall of armor being 6½ inches, while back of the guns runs a wall of 3-inch armor To reach the bases of the smokestacks a shell would have to pass through 9½ inches—an unprecedented but, as the Japanese war showed, a necessary protection Between each pair of 5-inch guns is a 2-inch transverse, splinter bulkhead.

The "Florida" will be driven by an equipment of Parsons turbines, working on four shafts. They are required by contract to develop 28,000 horse-power, which, it is estimated, will enable the ship to maintain an average speed of 20 75 knots on trial As a matter of fact, she is likely to do from three-quarters to a knot better than this. The "Florida" will store, in addition to 2 500 tons of coal, some 400 tons of oil fuel. Our naval constructors have long recognized the value of oil as an auxiliary fuel, and as far back as 1907, when the plans of the "North Dakota" and "Delaware" were drawn, provision was made for storage of oil, the ships of that class carrying 400 tons.

The keel of the "Utah," built by contract with a private yard, was laid on March 15th, and the keel of the "Florida" on March 7th The "Utah" was launched on December 23rd, 1909, at the 50 per cent stage of completion, and the "Florida" on May 12th will take the water with 68 per cent of the work completed, a comparison which establishes once more the much-contested claim of the Brooklyn Navy Yard that it can build as rapidly as the private yards.

## The Lubricating Value of Mineral Lubricants at High Temperatures.

The behavior of a mineral lubricant at very high temperatures is dependent upon its chemical and physical properties upon the nature of the atmosphere with which it is in contact—dry air carbon dioxide, or water vapor—and upon the pressure of this atmosphere Schreiber in a recent article describes his investigations of the lubricating value of mineral lubricants of very high melting points, in various conditions The diminution of the lubricating power at high temperatures is due to the evaporation of a portion of the lubricant and to the formation, by oxidation, of compounds of the nature of asphalt, i. e., compounds insoluble in benzine It is not due to polymerization, as is generally believed This increase in asphaltic matters is not produced in the presence of water vapor alone, even at a pressure as high as 7½ atmospheres. In this case the diminution of the lubricating power is due solely to the evaporation of part of the lubricant. On the other hand, when the lubricant is in contact with a gas which can exert an oxidizing action, compressed air, for example, the formation of these insoluble compounds is the chief cause of deterioration Schreiber deduces from these experiments laboratory methods of measuring the lubricating power at high temperatures, according to the class of machine in which the lubricant is to be used

## The Current Supplement.

The current SUPPLEMENT, No 1792, contains an unusual number of interesting illustrated articles Mr Harold Holcroft contributes a splendid paper full of practical suggestions and helpful ideas on the principles of vitreous enameling of cast iron for industrial purposes Mr Henry A Wise Wood's excellent review of modern stereotypy methods is continued Rear Admiral R H S Bacon critically considers the armorclad, and points out what type of vessel is likely to be evolved from it in the future The North African region lying in Algeria and Tunis affords almost an unlimited field for archæological research. Some recent discoveries in this country are described in an illustrated article by the Paris Correspondent of the SCIENTIFIC AMERICAN It is very difficult to recognize stars by studying the star maps and then seeking the stars marked on the maps Mr F R Russell, in an article entitled "Where to Find the Stars," provides the necessary link between the star maps and the sky A table of aeroplanes at Olympia is published, with some observations on the theories of flight. The food supply of the future is considered by H B Armsby

La Lumière Electrique publishes a series of articles reviewing the effects of the great Paris flood in January, 1910, upon the electric stations, telegraph, telephone, and electric light service of Paris and its suburbs. The St Denis establishment escaped inundation owing to its judicious arrangement of pumps and sluices and its elevation above the ground, and continued in operation without any interruption. Most of the other plants were less fortunate. Even the new underground wireless telegraph station at the Champ de Mars was submerged for several days, and its delicate apparatus was very seriously injured.

### WHY WATCH SPRINGS BREAK.

To the Editor of the SCIENTIFIC AMERICAN

It was with an amateur's interest that I read the discussion in your pages as to "Why watch springs break." As the question apparently still remains unsettled, I feel tempted to contribute some additional views on the subject.

Formerly clock springs were finished very rough, giving the convolutions considerable frictional grip upon each other For this reason, when running down, there was a very audible shuffling sound within the clock every few minutes, indicating the propelling force was spasmodic. Not only so, but the ticking sound of the escapement decreased in loudness as the time was prolonged from the last loosening of the coil. To regulate this it occurred to me to apply a more unctuous lubricant to the spring to prevent the said friction. The result of so doing was a gratifying uniformity of tick—but only for a few hours—until the spring broke

After the third experience of this kind I ceased to regard it as a mere coincidence, and thereafter applied no oil if there was sufficient to prevent rusting already on the steel.

The uncoiling of a watch spring and of the kind of clock spring that has just been described differs in that the watch spring unwinds from the outside of the coil, while the clock spring arbor backs up and unwinds from the center of the coil For this reason the latter is not subjected to a breaking from contraction due to cold, as there is always some room for the contraction to take place—excepting a possible momentary period just after winding The same is not the case with a watch spring.

If over-lubrication is destructive to the structure of steel in a clock spring, by rendering all the convolutions continually active and under unremitting strain, the same would also apply to a watch spring Watch springs being smaller than those intended for clocks are naturally proportionally stronger and may endure the strain longer, but that it is detrimental is probable. But oil on a watch spring is absolutely necessary solely to provide for this thermostatic movement which can only take place back and forth, to and from a fixed point—the arbor Yet the wearying strain on a spring due to over-lubrication can only be a contributory cause to the prevalent breaking of this part. Experience goes to show that the most frequent time for breakage is from an hour to three hours after winding, and that the most frequent position of fracture is just outside of the annealed tip attached to the arbor

Thus the owner takes his watch from his pocket where its temperature was, say 80 deg, and winds it until it brings up hard The coil is then central and solid upon its arbor, which is held fast by a pawl and ratchet

In a little while the wearer of the vest containing the watch removes it, hanging it on the back of a chair while he retires for the night The temperature of the watch gradually falls to say 60 deg Has contraction been provided for? The morning will disclose. If the coil has not been wound too tightly on, if some time has elapsed before cooling to enable it to draw on what has been paid out, or even if the rate of cooling and consequent contraction has not exceeded the rate of release due to the movement of the works, the spring may escape But what surprised the writer is not the breakages but the length of service many springs attain

When one considers that the greatest movement of contraction is on the outside of the coil, because of its greater area, that the coil has just been rendered taut and rigid by winding, and that then a powerful contracting force is added thereto, principally on the outside of the circle where the leverage is greatest, it is not difficult to realize what an unendurable strain takes place close to the fulcrum, the arbor, for the spring is then but a solid lever

The fracture of a spring in many places is also not hard to understand, if we imagine a spring stretched to its elastic limit by contraction from cold with no slack to draw upon, each turn of the spring, from the outside inward, at an ever-increasing tension An inner turn snaps, instantly contracts, and by that process increases the spreading or expanding trend of its temper. The change is altogether too rapid to permit of any uncoiling movement, and the force thus added to the adjacent surrounding strand fractures that, gathering force with each succeeding fracture until, like a "Prince Rupert's drop," the pent-up strain comes to rest with explosive suddenness.

That the pieces display magnetism does not necessarily indicate that it was produced from external influence, but rather that it was evolved by excessive strain and retained by the steel by virtue of its hardness, as is similarly evidenced by many machinists' tools subjected to severe service.

Regarding the preference of springs to break in the summer months, is it not sufficiently evident from the following three causes?

1 The more constant and wearying strain due to the better lubricating effect of warm oil.

2 The increased solidity of the coil when wound up, due to a thinner film of oil between the convolutions, also due to warmth

3 The looser texture and greater proportional shrinkage of a warm spring compared with a cool one

As to the remedy for this uncertainty of time-keepers, it would seem sufficient to provide for the longitudinal expansion and contraction of the springs, and the simplest way would be to make them of metal insensitive to these changes. Such an alloy has been described in SCIENTIFIC AMERICAN SUPPLEMENT, No 1714, by M Guillaume, which he calls "Invar" and is composed of steel with an admixture of 36 per cent nickel It is used for spiral springs, pendulums and graduated scales for instruments. The fact that it does not rust should complete its adaptability to this purpose, as then it could be used without lubricant and thus, except for a short portion at one time, be relieved of continuous and active strain

Just how the nickel component will affect its permanency of temper remains to be proven, but even if it retains sufficient recoiling force for its purpose for five years only, it would at least give warning of its waning strength and not leave its owner in the lurch, which is perhaps all the improvement needed

Another possible remedy which modern practice would indicate as quite feasible would be to carbonize the rods or plates, from which the springs are drawn, from one side only The result would be, when chilled, a hard side (for the inner side) and a soft or elastically tough side (for the outer side) with a general benefit of greater spring power with improved tensile strength

Watchmakers will tell you that the breaking of main springs saves many good watches from having their pivots cut off, from shear wear, and the views of the manufacturer need not be consulted but the ordinary citizen would prefer to have the spring as reliable as the rest of the watch JAMES E FRASER.

### INTERESTING MAGIC SQUARE.

To the Editor of the SCIENTIFIC AMERICAN

In the December 11th issue of the SCIENTIFIC AMERICAN (page 436) Mr A Galpin gives an interesting construction of magic squares, containing all the odd

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| 42 | 34 | 26 | 18 | 1 | 74 | 66 | 58 | 50 |
| 52 | 44 | 36 | 19 | 11 | 3 | 76 | 68 | 60 |
| 62 | 54 | 37 | 29 | 21 | 13 | 5 | 78 | 70 |
| 72 | 55 | 47 | 39 | 31 | 23 | 15 | 7 | 80 |
| 73 | 65 | 57 | 49 | 41 | 33 | 25 | 17 | 9 |
| 2 | 75 | 67 | 59 | 51 | 43 | 35 | 27 | 10 |
| 12 | 4 | 77 | 69 | 61 | 53 | 45 | 28 | 20 |
| 22 | 14 | 6 | 79 | 71 | 63 | 46 | 38 | 30 |
| 32 | 24 | 16 | 8 | 81 | 64 | 56 | 48 | 40 |

numbers in the inscribed diagonal square But this construction is applicable not only, as Mr Galpin says, when the basis is a prime number, but more generally when the basis is an odd number (1, 3, 5, 7, 9, 11, ) The proof is very easy there is here the square of 9, an example of the simplest odd number not prime the general proof is an interesting exercise of algebra. DR. G VACCA

Genoa, Italy

### HYDROGEN IN A HOT-WATER SYSTEM.

To the Editor of the SCIENTIFIC AMERICAN

A short time ago I noticed a phenomenon which I believe will be of interest to many of the readers of the SCIENTIFIC AMERICAN

The main building of our experiment station here is heated with hot water It has been one of my duties to see that the system is working properly, and in this connection I have had to open the air vents on the radiators frequently I was surprised to find that the radiators on the top floor (a two-story building) always seemed to have air in them, in spite of the fact that the system was fully charged and very little or no new water admitted I began to suspect that this condition had to be accounted for in some other way Was there not a possibility that this gas could be hydrogen? For what other gas would be likely to form under those conditions, unless it be a trace of carbon monoxide? At any rate, when I applied a match the gas lighted with the familiar pop of hydrogen and burned with its characteristic almost colorless flame Assuming that the gas is hydrogen (I have no means of testing it) the question suggests itself Is this a case of oxidation of the iron setting free hydrogen? Is it an electrolytic effect, caused by galvanic couples of either carbon and iron or iron and the brass connections in the system? Or is the gas methane? It may be noted further that the gas does not seem to collect in the radiators in the lower floor to a great extent, if any Of course, this may be due to the gas being dissolved under the increased static pressure The static pressure on the radiators of the top floor is not over ten feet of water at the present time The water is of exceptional purity, being supplied by a spring The fact, however that small quantities of water have to be added occasionally to replace the leaks in the system might suggest the presence of methane That question can only be settled by chemical analysis

Puyallup, Wash C WESTERGAARD

### AN EARLY APPEARANCE OF ENCKE'S COMET

To the Editor of the SCIENTIFIC AMERICAN

The change which has come to the people in reference to comets is worthy of notice Seventy years ago when Encke's comet made its appearance a great deal of fear was aroused I was a young boy, but remember very well the alarm of the people It was indeed very strange and portentous, for it switched about from the zenith to the horizon, and was very brilliant *Its color varied from a light to a fiery red*, and its length was such that it stretched from the zenith to the horizon It hovered so long and was so conspicuous that all classes, young and old, were greatly impressed About that time the Millerite excitement prevailed, and there were many who looked upon the comet as a sure sign that the world was surely coming to an end There have been other comets which impressed the people but this exceeded all others in the impression made

Salem, Mass STEPHEN D PEET

### A New Sense Organ of Butterflies.

Every butterfly collector has had the unpleasant experience that some butterflies, and particularly those of the species of Catocala (mourning cloak) will notice his approach from a distance and fly away in time This observation led Tetens to think that these animals must have an auditory organ which warns them of approaching danger by receiving sounds, and accordingly he expressed the supposition that two pitlike depressions at the first posterior segment of the body might be organs of hearing A thorough investigation of this organ, however, has been made but recently by Prof Dr Deegener, the results being published in Zoologische Jahrbücher, Abteilung für Anatomie, vol 27, No 4 1909

It is rather surprising that with a group so frequently collected (although indeed investigated, as a rule only as to their position within a system) as the Noctuidæ, an organ could escape observation which is found quite generally in this group and which is by no means microscopic, but can be observed without difficulty with the naked eye as a striking formation on each side of the first abdominal segment This location probably explains why this organ should have been seen by many persons without arousing the suspicion that it could be a sense organ, for naturally enough such organs are looked for chiefly at the head, particularly at the feelers, although other parts of the body may be the seat of specific sense organs, for instance, grasshoppers have their organs of hearing at the base of the abdomen, that is at the same place where the corresponding organ of the Noctuidæ has been discovered

When examining the animal we see on each side at the line separating the chest from the abdomen and near the points where the rear wings are attached, a deep channel which toward the surface is surrounded by several humps The external morphology of this organ varies in details with the different species of Noctuidæ, with some the opening is scarcely visible from the outside being concealed by long hairs set close together The microscopic examination of a series of sections shows that only one of the ridges in the vicinity of the cavity of the organ, the one nearest the back, can be considered a "sensitory ridge," but that this one has true sensitory cells and sensitory hairs and thus gives the organ the character of a sense organ Tetens's supposition, mentioned above, that this is an auditory organ may very well be maintained since the structure of the organ answers all the requirements of an organ of hearing Still experimental confirmation of this hypothesis will have to be awaited Dr Deegener promises a further report, dealing with this phase of the subject.—Prometheus

Approximately 3,748 miles of new main track were built in the United States during the year 1909 as compared with 3,214 miles for 1908 The 1908 record was the smallest since 1897, when 2,109 miles were built These figures do not include new second third or fourth track sidings or electric lines The net increase during the year is about 16½ per cent, and 28 per cent less mileage was built than in 1907

# REINFORCED CONCRETE WATER WORKS CONSTRUCTION

BY FRANK C. PERKINS

The accompanying views of the Indianapolis water works show an interesting application of reinforced concrete to this class of construction A gravity flow supplies the reinforced concrete filter plant from the Indiana State Central Canal which was constructed originally by the State for transportation purposes, but was taken over for water works service At a distance of about 6 miles above the intake to the filters are located the head gates and concrete sluice ways of this canal which is carried over Falls Creek near the filter plant in an open aqueduct at an elevation of about 18 feet above the creek

The chemical house columns, floors and walls as well as stairways and roof are of reinforced concrete throughout. The lower part of the building contains the lime saturating tanks over which are constructed the iron solution tanks all of which are of concrete They are used in connection with the coagulating basins in the treatment of the raw water during seasons of excessive turbidity

The following account of these works is based upon data furnished by the constructing engineer, William Curtis Mabee The water, which is drawn from the Raw River is clarified by coagulation in precipitation basins, which are provided with baffle walls spaced 70 feet apart and which are reinforced for the prevention of cracks A 4 inch slab of concrete, reinforced with twisted rods spaced 4 feet apart in each direction is used for lining the sloping embankments of earth while the slab floor, laid in blocks 8 feet square, is 4 inches in thickness

The water is measured in a Venturi meter, 42 inches in diameter which has a throat diameter of 21 inches The meter is built in the raw water conduit the indicating apparatus being located in the laboratory

A reinforced concrete pipe line which is 840 feet in length, and has a diameter of 66 inches, and a shell 6 inches thick, conducts the raw water to the precipitation basin The pipe is laid 11 feet below the hydraulic gradient It is reinforced with ½-inch twisted bars spaced 8 inches on centers, the shell of the pipe being built in three operations.

In the construction of the conduit a concrete cradle 30 inches wide was first laid to grade In this were imbedded the lower rods, which were heated and bent in the field to the required shape, and left long enough to project a foot into the upper ring On the cradle were then placed the semi-circular metal forms, which were fastened down by staked timbers. The mixture of cement, in the proportion of 4 of gravel, 2 of sand, and 1 of cement, was poured into the space forming the lower half of the pipe The upper half was then constructed by inverting the metal forms. The cost of the pipe, which contained about 300 cubic yards of concrete, was $12 46 per cubic yard

The pure water reservoir, with a capacity of 5½ million gallons, was built near Falls Creek, on a gravel foundation, at ordinary ground water level. The earth filling is 2 feet deep on the cover, the weight of the structure itself overbalancing any upward pressure that may occur The groined arch bottom was designed to resist the upward thrust of high ground water at such times as the reservoir is empty, the inverted groined arch construction distributing the load uniformly over the bottom. The reinforcement of the bottom consists of ½ inch twisted bars, spaced 10 inches on centers in each direction

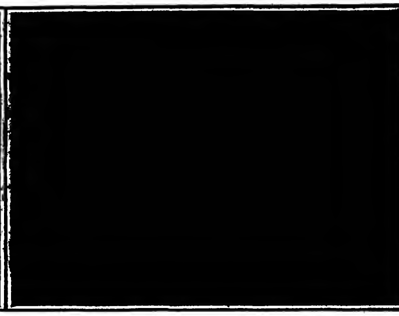
The filter cover consists of reinforced 3 inch slabs, supported by concrete beams, a trifle less than 20 feet long, and spaced nearly 7 feet on centers. The beams are 8 inches in width and 15 inches deep. They are carried on 18-inch I-beams, incased in concrete and bolted to the columns. The reinforced partition walls, 1 foot thick, are 350 feet in length. They are reinforced in both directions, and measure 14 to 17 feet in height. The entire slab covers 70,000 square feet in each double filter It is built monolithic, without any attempt to provide expansion joints. A cable tramway with a span of 450 feet was used in the construction A stationary engine and cable was used for propelling a shuttle car on a narrow-gage track, over which the concrete was handled from the mixer to the cableway, 80 cubic yards per day being used in covering 5,000 square feet of surface The cost of the filter covers was $14 65 per cubic yard, and the cost of the walls $12.06

The reinforced concrete aqueduct, 300 feet in length, contains 4,500 cubic yards of concrete, which cost $6 52 per cubic yard including the cement, steel, sand and gravel, as well as the lumber, forms, labor, and concrete labor It is 41 feet wide and has four spans of 60 feet each with a 10-foot rise from the springing line to the soffit, and a crown thickness of 18 inches for each of the four segmental arches.

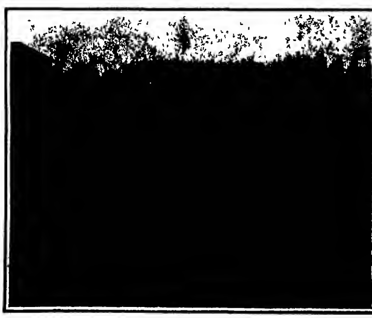
The foundations for the piers, wing walls and abutments were carried down 16 feet below low water, and rest upon a bed of sand and gravel The aqueduct takes the place of a wood aqueduct, which was supported by steel trusses on masonry piers, all of which were carried away by a flood which undermined the middle pier, the superstructure breaking up as the substructure crumbled away

With regard to the use of concrete for works of this character, Mr Mabee, the constructing engineer of these water works, makes the following comments:

View showing construction of the groined-arch floor, with the reinforcement and forms in place



Operating floor of the chemical house in which the water is purified in lime and iron saturating tanks.



Steel reinforcement of the 66-inch conduit.

The central concrete plant for mixing the concrete.

REINFORCED CONCRETE WATER WORKS CONSTRUCTION.

Concrete has many advantages over other types of construction. It is easily and conveniently handled and transported, often at a less cost than stone masonry, and often suitable sand and gravel for the work in hand can be found on the site. With proper supervision, skilled labor is not essential in the usual work, moreover, the art of mixing and handling concrete has been so perfected that machines do most of the work. Concrete has the additional advantage over stone that it may be molded into intricate shapes.

To produce concrete surfaces of a satisfactory smoothness and uniformity, it is necessary that the molds be carefully and properly built, and also that the concrete be of the proper consistency to flow readily into the prepared molds. It is also necessary to thoroughly churn and keep it in motion in the molds until the air has been removed and every crevice filled with mortar. Properly handled in this manner, it will not be necessary to brush or plaster the work after the removal of the forms. Concrete may be placed in moderately freezing weather, provided proper precautions are taken to warm the gravel or stone and sand, to heat the water and to cover the work until initial set takes place.

The problem of preventing ugly cracks forming in concrete is one that has worried many engineers. Plain concrete is liable to crack where you least expect it, and it has become the practice to provide for those cracks by building short sections in alternate blocks. However, by the judicious introduction of steel bars, objectionable contraction cracks can be entirely eliminated.

The water works engineer or superintendent is particularly interested in the subject of waterproofing concrete. It has been shown that wet concrete is more dense and consequently more impervious than dry concrete and that concrete becomes more or less porous as the quantity of cement is increased or diminished. A smoothly troweled surface produces a water-tight film or skin. It has also been found that slaked lime added to the concrete mixture helps to make it less permeable. The lime does not injure the cement in any way, although retarding the setting. Coal tar, pitch and asphalt mixtures applied on concrete are used with more or less success. A wash composed of one pound of lye, five pounds of alum and two gallons of water, applied with a brush and well rubbed in, has been used successfully on government fortifications.

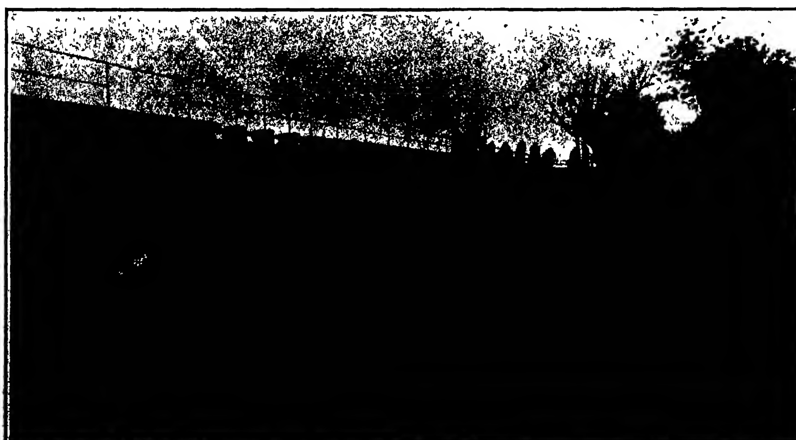
A rich cement mortar plastered over concrete makes a very good waterproofing medium. Proper attention to these details will produce a water-tight structure, if there is not likely to be contraction cracks, but in works of any magnitude these are bound to occur and they can be best provided against by the introduction of steel bars. A rich concrete properly reinforced, coated with plaster and troweled smooth makes an ideal waterproof structure.

Covered reservoir under construction, showing the ground floor, the reinforced slab roof, and the supporting columns.

### The Daylight Efficiency of Artificial Illuminants.

In a recent publication of the Bureau of Standards, Mr. H. E. Ives suggests that there is need of some method of estimating the resemblance of artificial illuminants to daylight, that is, of determining their daylight efficiency. Assuming that, by the extraction of certain qualities of light in an illuminant its color could be brought to resemble that of daylight very closely, the daylight efficiency of a source might be expressed in the form (intensity of available white light)/(total intensity of source). Mr. Ives suggests two methods of studying this question. The first is based upon the use of suitable absorbing screens which, as explained above, could be used to bring the color of an illuminant into near agreement with daylight, though reducing its intensity in doing so. Mr. Ives presents some spectrophotometric curves of various sources of light, and a diagram illustrating the amount and nature of light from the various sources which must be absorbed to produce white light. He also tabulates the "daylight efficiency" of a number of artificial illuminants. The method, however, is of practical rather than of scientific interest since it depends upon the particular wave-length for which the intensity is assumed to be unity, when plotting the spectrum curves. In addition, "selective" sources such as the mercury arc lamp which yields a spectrum consisting of isolated bright lines, would work out to zero efficiency according to the above method. Yet if we judge by sensation such sources contain a certain amount of white light. Mr. Ives then proceeds to discuss a second method based on the fact that any color can be matched by a mixture of white light and one ray of the spectrum. The ratio of the white light used in attaining such a match to the intensity of the source studied is then regarded as an alternative method of defining white light efficiency which Mr. Ives in this case terms "white sensation efficiency." He points out that classification on this method gives rise to materially different results from those arrived at by the former method. The efficiency in the case of the second method appears to be higher. Yet the result gives no indication of the ability of the source to reveal colors of surrounding objects, and merely indicates the color of a white surface illuminated by the source. In conclusion, Mr. Ives remarks that the first method is preferable from the practical standpoint, and the latter from the purely scientific one.

It is estimated that the Gold Coast and Ashanti could supply 60 843 logs of mahogany and cedar per year if the internal communication were better. With mechanical haulage, such as traction engines and light tramways, the output could be increased to some 250 000 logs per annum without depleting the natural reserves.



Aqueduct by which the water is conducted to the filter plant of the Indianapolis water works.

REINFORCED CONCRETE WATER WORKS CONSTRUCTION.

# THE HEAVENS IN MAY

BY HENRY NORRIS RUSSELL

IT is seldom that so much of interest to the amateur astronomer happens in a single month as in the one which is just before us

First and foremost, of course, is the return of Halley's comet to the position where it is seen to the best advantage Early in the month it is favorably placed for observation before day break, on the 18th it passes directly between us and the sun, and later it appears to even greater advantage in the evening sky

At the beginning of May the comet is about 74 million miles away, but it approaches us rapidly, its distance diminishing to 41 million miles on the 10th, and 27 million on the 14th As it was about at the limit of visibility to the naked eye on April 12th, while still 135 million miles from us, it is now a fairly conspicuous object

The planet Venus is fortunately near by and serves as an excellent "pointer" to the comet. Anyone, however little familiar with the heavens, can easily find the latter by observing the following directions

Choose a window from which the eastern sky is visible clear down to the horizon Rise about 3:15 A M and look due east. The very bright starlike object, low down in the sky, is Venus The comet is to the left of this and a little higher up at a distance about as great as the length of the bowl of the Great Dipper It will probably be rather fainter than the four stars, forming a great square, which lie above and to the left of Venus, about twice as far away as the comet.

These directions hold good from May 1st to May 12th On the 14th the comet will be on a level with Venus, and a little farther to the left On the 16th it will be much lower than the planet and about 20 deg to the left. After this the comet, or at least its head, can hardly be seen clear of the morning twilight

It will be very interesting to watch the comet grow larger and brighter night by night as it comes nearer to us How long its tail will be it is impossible to predict. The best time to see this however, will in any case be from the 7th onward, when the moon is out of the way and the sky dark The comet will be larger and brighter, too, at this time than previously

Even after the head gets too near the sun to be seen, the tail may be observable in the mornings of the 17th and 18th extending upward and to the right from the eastern horizon, perhaps broad and fan-shaped, from the effects of perspective since the end of it will be much nearer us than the head

On the evening of the 18th or morning of the 19th (according to the observer's longitude) the comet passes between us and the sun, and the earth will be enveloped in its tail if the latter is long enough (over 15 million miles)

If this evening is clear it will be of great interest and importance to look for illumination of the sky In the early evening, just after sunset, the comet's tail will be in the east, but a few hours later it will have passed over toward the west. If, as is sometimes supposed the tail is a hollow cone of light, there will be two times at which the sky in general is comparatively brightly illuminated separated by an interval while we are in the darker center of the tail Meanwhile, observers on the opposite side of our planet will have the rare privilege of seeing the sun through the comet's head Only the extreme western portion of the United States is included in this favored region, but as the comet enters upon the sun's disk at 6 23 P M by Pacific standard time and remains on it till 7.22, the transit will be visible all along the coast. The comet passes almost squarely across the center of the sun from west to east.

Paradoxical as it may seem, it is probable that the ordinary observer, even with a small telescope and dark glasses, will not be able to detect even the slightest trace of the comet's passage With powerful instruments the nucleus, if solid, might be seen as a dark speck against the sun, if it is over 50 miles in diameter, but it is improbable that it is anything like so large, for, as has already been stated in these columns, the whole amount of light reflected from the comet, when remote from the sun, is no more than a single mass 30 miles across would send us.

It is possible, too, that the absorption of the gases composing the envelopes of the head and the tail may be detected by means of the spectroscope, and as we will be looking through the tail lengthwise, nearly 15 million miles of it will be there to exert any possible effect on the sun's light. Even so, it will not be surprising to many astronomers if nothing unusual is detected.

Such negative results will however be scientifically valuable, since they will enable us to say that the materials composing the comet do not exceed certain limits of mass or density

Transits of comets across the sun are very rare. The most remarkable previous instance is that of the great comet of 1882, which, though so bright that it could be seen close to the sun in broad daylight with the naked eye, vanished completely when in front of the sun's disk, showing that it was practically perfectly transparent

On the evening of the 19th we may perhaps already see the comet's tail in the evening sky, though its head will set while the twilight is still very strong. On the 20th, however, it will be visible till about 9 P M., on the 22nd till 10:20, and on the 25th and afterward until after 11 P M.

On the 21st the comet's head will be close to the star γ Geminorum; on the 23rd about 10 deg above Procyon, and on the 25th near ε and ζ Hydrae Fuller details will be given later

This month is also notable for two total eclipses of the sun on the 8th and of the moon on the 23rd. The former is an important eclipse, the maximum duration of the total phase being over four minutes, but unfortunately the track of the shadow lies almost entirely in the Southern Ocean, only crossing the southern half of Tasmania, so that few stations are available for observers. As a partial eclipse it is visible throughout Australia, New Guinea, and the neighboring islands.

The lunar eclipse of the 23rd is of more interest to us, being visible throughout the United States, excepting Alaska. The moon enters the earth's penumbra at 9:32 eastern standard time, and first touches the shadow at 10 46. At nine minutes after midnight she disappears in it completely, and does not emerge till 1 A.M At the middle of the eclipse, however, her southern edge is only about 200 miles inside the shadow, so that it will be considerably illuminated by sunlight refracted through our atmosphere. At 2 23 A.M the moon takes leave of the shadow entirely, and at 3 36 of the penumbra. This eclipse will be of importance to observers on the Pacific coast, as it will give them a chance to photograph Halley's comet on a dark sky The comet will have set for [illegible] in the east before totality comes on

At 10 o'clock Apr 22.

At 9½ o'clock April 30.

At 9 o'clock May 7
At 8½ o'clock May 15.
At 8 o'clock May 22.

NIGHT SKY: APRIL AND MAY

THE HEAVENS

With so much else to engage our attention, our glance at the stars must be short. The most prominent constellations in the west are Gemini and Canis Minor, in the northwest, Auriga, due north, Cassiopeia below the Pole, Ursa Minor and Draco above, and the Great Bear almost overhead. In the northeast Lyra is prominent, and in the east Hercules, Corona, and Boötes. Scorpio is rising in the southeast Due south is Virgo As our initial shows, there is not the slightest resemblance in the stars to the figure for which they were named

We may note the bright star Spica, a spectroscopic binary at a great distance from us, and the double star γ (now close to Jupiter) which is now separable with a small telescope, but in 1835 could hardly be seen double with the largest instruments then existing The two components were then at the closest point of the very eccentric orbit, in which they revolve about one another in some 180 years.

THE PLANETS.

Mercury is evening star until the 25th, when he passes through inferior conjunction, between us and the sun, and becomes a morning star He can be best seen at the beginning of the month, when he sets more than 1½ hours later than the sun. At this time he is in Taurus between Aldebaran and the Pleiades, and should be easy to see.

Venus is morning star, rising a little after 3 A M and exceedingly conspicuous all through the month Mars is evening star in Gemini, setting about 10:30 P M. in the middle of the month, at which time he is quite close to the star ε Geminorum (shown on map)

Jupiter is well past opposition, but is visible most of the night, remaining in sight till nearly 4 A.M. on the 1st, and till a little before 3 A.M. on the 31st.

Saturn is morning star in Aries, rising about an hour earlier than the sun in the middle of the month and two hours at its end; but it is too low to be conspicuous.

Uranus is in Sagittarius, and comes to the meridian at 4 A.M on the 19th. Neptune is in Gemini, observable most of the night. On the 29th he is in conjunction with Mars, being 1 deg. 59 min. south of the latter. This may be a good chance for amateurs with

(Concluded on page 383.)

# NATURE AS AN INVENTOR

BY PERCY COLLINS

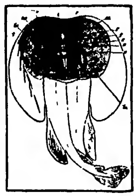
Civilized man justly prides himself upon his numerous inventions and mechanical devices, but it is possible that inventors in general would boast less of their achievements did they realise that the patents in which they have established their rights are really nothing more than modern reproductions of devices which have been employed by Nature from the beginning of time. It is a fact that there is scarcely an invention of man that has not its prototype in Nature. Sometimes these prototypes are of a rough-and-ready character. More often, however, they have been brought to the highest pitch of perfection. It is little short of amazing that primitive man should have remained blind, through so many centuries, to the significance and value of these inventions of Nature. It has been said that almost all of man's achievements as an inventor have their prototypes either in the animal or vegetable kingdom. Obviously, therefore, it would be impossible to attempt—in the limits of a short article—anything approaching a complete catalogue of these coincidences. Yet a few of them may be selected, almost at random, and they will serve to show how, after much labor and thought, man has perfected devices which at the time appeared to him to be original, although in reality they were nothing more than reproductions.

As a first instance we may take grasping tools—a whole tribe of implements ranging from surgical forceps and sugar tongs to gasfitters' pliers and the vast pincers by means of which great masses of white-hot metal are manipulated upon the giant anvils of our workshops. It is scarcely too much to affirm that, without such tools as these, art, science and manufacture would long ago have ceased to advance. The reader needs only to pause for a moment to realize how important a part is played by these familiar implements in the activities of human life, and when mankind first discovered how to make and use such things he must have benefited instantly. Yet all these tools have their parallels in Nature, and one is fain to imagine that some of these prototypes might still supply useful hints to modern toolmakers. Perhaps the most perfect example of the powerful pincer in Nature is the claw of a crab or a lobster. The power of the crab's claw is so great that a bite from a large crab will inflict a severe injury. It is related that fishermen who have been feeling for crabs in the recesses of the rocks at low water have occasionally had their hand seized by a large specimen, and being unable to liberate themselves have been drowned by the returning tide. Among other pincer-carrying animals are scorpions, while the insects known as earwigs carry a dainty pair of forceps at the end of the body, and employ the tools for folding their ample and delicate wings. The opposable thumb and forefinger constitute, in effect, a most useful pair of pliers adaptable to many uses, and it is strange that man should so long have overlooked the lesson in mechanics which they teach. Shears and scissors are of course closely allied in principle to grasping tools, yet they have come to us only with the advance of civilization—no savage tribes having the least idea of them or their

(Continued on page 383.)

The first bottle—a gourd

The first ball-and-socket joint—a human shoulder



Nature's electric battery—the electric ray or torpedo.

The first spinners—a moth whose caterpillar spins the cocoon

The first pump—a heart

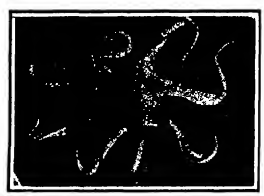
One of the first boxes, a receptacle which holds Brazil nuts, so cleverly packed that, if once taken out, no human hand can put them back again

The first hypodermic syringe. The arrangement of lance and saws by which the female mosquito makes and enlarges a puncture. The instruments assembled form a tube through which venom is injected

The first balloon—the "swell-fish," which is said to inflate itself with air and skip over the water, impelled by the breeze

The lantern fly of tropical America. Light without heat—the illuminating engineer's ideal.

The first seamstress. The tailor bird, which stitches the leaves of her nest together



The first "cupping apparatus"—an octopus

The egg of the murre. A box that cannot roll off a shelf. If disturbed it rolls around and around.

A lobster's claw. The original of a gas-fitter's pincers.

The first hinge. The thorny oyster of the Pacific, whose hinge is as good as that found in any hardware shop

NATURE AS AN INVENTOR.

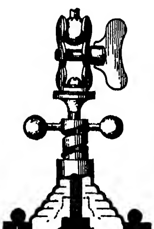
# CURIOSITIES OF SCIENCE AND INVENTION

### SUCTION BRACKET FOR MIRRORS.

There is nothing very novel in supporting a device on a smooth surface by means of a suction cup. However, the suction support illustrated in the accompanying engraving is provided with a very ingenious

SHAVING MIRROR ATTACHED TO A WINDOW PANE WITH SUCTION BRACKET.

method of producing an efficient vacuum. The photograph shows a shaving mirror secured by means of a ball joint to the suction bracket and the bracket is supported on a window pane. So tightly does the device adhere to the window that it is possible to raise the window by lifting the bracket. The bracket cannot be pulled off the glass without danger of breaking the window pane. The line drawing shows a sectional view of the bracket, and illustrates the method of producing the suction. The base of the bracket is provided with a rubber disk, the center of which is secured to a square shaft on which the mirror is supported. Mounted on this shaft and free to turn thereon, is a sleeve in which a spiral groove is cut to receive a pin projecting from the square shaft. The sleeve is provided with a pair of ball knobs by which it may be gripped and turned, forcing the shaft outward and thus cupping the rubber disk as indicated by dotted lines. There is no possibility of leakage except under the edge of the disk. A bracket thus applied will adhere firmly for weeks at a time. The stand may be secured to any smooth surface and is particularly adapted for a shaving mirror because it may be placed directly on the window pane where the best light for shaving can be obtained.



THE MIRROR BRACKET BROKEN AWAY TO SHOW THE SUCTION DISK

### THE OLD "INVICTA" LOCOMOTIVE AS A MONUMENT

A public monument of interest to all who make a study of the evolution of the modern locomotive has recently been set up in Canterbury, England. Fixed on a pedestal beneath the Norman walls of the historic city is the old "Invicta" engine, which in May, 1830 hauled the first train on the Canterbury to Whitstable Railway—the pioneer iron road of the south of Britain. The locomotive was built by George Stephenson. It will be observed that the cylinders and valve chests are very similar to those on the modern locomotive. The cylinders are 10 inches in diameter with an 18-inch stroke. The wheels are 4 feet in diameter. The boiler is 10 feet long by 3 feet 4 inches in diameter, and the working pressure was 40 pounds per square inch. The locomotive is now the property of the Corporation of Canterbury. It is coated with a special preservative paint.

GEORGE STEPHENSON'S "INVICTA" NOW SET UP AS A MONUMENT

### THE TELESCOPE THAT FIRST PICKED UP HALLEY'S COMET

The large reflecting telescope illustrated herewith is interesting by reason of the fact that it was the first instrument to pick up Halley's comet on its present visit to our circle of the solar system. To be sure, the comet was discovered on photographic plates made with other telescopes before the photographic record made with the reflector here shown. But it was Prof. Max Wolf who first identified the comet on a photograph taken with this reflector at the Heidelberg Observatory. The discovery was made on September 1st, 220 days before perihelion. The Heidelberg reflector has a focal length of 9.18 feet, and the diameter of the mirror is 28 inches. The

THE TELESCOPE WITH WHICH HALLEY'S COMET WAS FIRST PICKED UP

mounting is thoroughly up-to-date, and is electrically controlled. The observation platform is adjustable vertically by means of an electric motor.

### A NEW COMPETITOR OF THE HORSE.

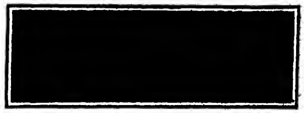
The "zebrass" has made its bow to the public. This creature is a new thing in the world, it never having existed until a year ago. It is the hybrid offspring of the African zebra and the Texas donkey. There are at the government experiment station at Bethesda, Md., six young zebrasses. Their sire is the royal Abyssinian zebra which King Menelik gave to

A VALUABLE HYBRID—A CROSS BETWEEN A ZEBRA AND A DONKEY.

President Roosevelt. The latter turned the striped creature over to the experiment station, and here the idea of developing a new race of animals was conceived. These six young ones are the nucleus. They are regarded as offering great promise. Certain of them combine the docility, strength and utility of the mother with the spirit, activity and beauty of the father. The yearlings are already larger than their mother. They are beautifully built and should be adapted to the many uses to which the domestic animal is put.

### TROCHA CUTTER

A soldier in the Spanish and Philippine wars, who had abundant experience in endeavoring to get through the wire entanglements of the Spanish trochas, has recently devised a very simple cutter which may be applied to the bayonet of the gun. A soldier in action will disencumber himself of everything except his gun



WIRE-CUTTING ATTACHMENT FOR GUNS.

and bayonet, and hence the pliers which are usually furnished for cutting barb wire obstructions are frequently thrown away, so that the only method of getting through an entanglement when encountered is to hammer the wire with the bayonet and a stone. Not only is this process slow, but it is fatal in a galling fire. For this reason the inventor has devised a cutter which may be secured to the bayonet without interfering with the use of the gun and which will operate to sever the wire by a single thrust of the weapon. As shown in the illustration, the cutter consists of two jaws pivoted eccentrically so that when extending forward in their normal position they are open, but when pushed back they close. In operation, the gun is inverted, the point of the bayonet is rested on the wire, and then the gun is thrust forward with the bayonet sliding on the wire so as to guide the latter between the jaws of the cutter. As the jaws are thrust back they close upon the wire and sever it.

### RÖNTGENOGRAM OF A FULLY DRESSED MAN.

The range of visible rays from deep red to violet forms a very small part of the solar spectrum. Beyond the red, the rays are too long to affect the retina, but we can detect them as heat. At the other end, we have the ultra-violet rays which are too short to affect the retina, but manifest themselves on the photographic plate. Röntgen rays are not found in sunlight, but if they were, and if our eyes were so constructed that they could detect only these rays, visible matter about us would take on a very different aspect from that to which we are accustomed. The accompanying illustration shows how a man would appear. The man appears semi-transparent and one can easily make out his two watches and chain, his tie clip and the buckles of his suspenders. The metal parts of the buttons on his coat are also quite evident, and his ribs may be plainly seen. A pickpocket might envy such power of discernment, but he would have difficulty in concealing his plunder if others were possessed of similar vision.

The photograph was taken instantaneously with a Snooks apparatus, and is reproduced from "Archives of the Röntgen Ray." Heretofore, it has required a long exposure to take a photograph with the Röntgen rays, but recently a system has been devised by which a very sudden and powerful discharge is produced capable of making an instantaneous photograph. This sudden discharge is made by using a fuse in place of the interrupter of an induction coil. The fuse is melted when the proper intensity of current is reached, producing a very sudden break of the primary and a powerful discharge of the secondary. Exposures of 1/50 to 1/120 of a second have thus been obtained.

The Sketch.

RÖNTGENOGRAM OF A FULLY DRESSED MAN.

## RECENTLY PATENTED INVENTIONS.

### Electrical Devices.

SAFETY DEVICE FOR ELECTRIC LAMPS.—J. W. Eisenmann, Kansas City, Mo. The invention refers to safety devices for use in incandescent lamps using filaments or other incandescent members, the more particular object being to continue the activity of the lamp in case a filament or its equivalent is broken, which would ordinarily extinguish the light altogether.

### Of Interest to Farmers.

THRESHING MACHINE FEEDER.—H. J. Boyer, Chester, Mont. The principal purposes here are to provide a spreading and feeding table for delivering to the draper of the machine the grain-bearing straw to be threshed; to provide a portable spreading and feeding table adapted to deliver the straw upon the draper of the machine as and when extended in opposite directions from the machine; and to provide a mechanism wherein the construction and arrangement are simplified.

HARVESTER.—H. A. Tuttle, Richland, Wash. This improvement has in view the provision of a harvester so constructed and arranged that it may be operated with a minimum amount of labor to cut the grain and transport it to threshing means where it is threshed and thereafter separated from the straw and chaff, the latter being carried to a straw dump and the grain carried to an elevated position where it is delivered into bags and the like.

PEA HARVESTER.—G. L. Pritchard, Lilly, N. J. In this instance the invention relates to machines for harvesting rice and the like, either from vines or stalks. It is of that type of device which is adapted to rake over the rows of plants, scoop in the vines, strip the peas or rice from the plants and then separate the peas or rice from the refuse.

COTTON CHOPPER.—T. A. Lang, Southmayd, Texas. In operation the machine is moved through the field with a wheel on each side of the cotton row. When in position the clutch sleeve is released, thus coupling the operating means for the swinging arm with the wheels. The arm is swung transversely of the row. By means of a lever the swinging frame and with it the swinging arm and the hoes may be lifted clear of the ground, or adjusted to engage the plants whether above or below the plane upon which the wheels travel. Means provide to leave the standing plants nearer together or farther apart.

### Of General Interest.

PRESS BED.—F. J. Lefever, Middletown, N. Y. The aim in this instance is to provide a bed having a construction which will enable printing plates to be set up thereupon at any desired point, and further to provide an arrangement which will enable the plates to be unlocked or removed at any point without affecting the "lock-up" of the entire bed.

BOILER BOTTOM.—D. J. Lahai, Coleman, Wis. The intention in this improvement is the provision of a false bottom with an improved construction which can be readily inserted in an ordinary clothes boiler so as to enable it to be used as a steam cleaner for cleaning lace curtains and other delicate fabrics.

BRUSH.—J. I. Faskine, New York, N. Y. The brush is made in sections capable of being readily taken apart for cleaning, sterilizing or renewing any one of the sections in case the same is worn out or injured, thus saving the cost of a new brush. Means provide for the ferrule being relieved of some strain when the brush is used, and this insures a strong and durable brush.

AMMONIA PURIFIER FOR REFRIGERATING PLANTS.—L. Wagner, Sedalia, Mo. The object of the invention is to produce a high grade of anhydrous ammonia continuously while the compressor is in operation, and he accomplish this by condensing and separating out the oil and water vapor carried along with the ammonia from the compressor.

INDEX.—R. W. Wood, Seattle, Wash. An object of this inventor is to provide an index by the use of which a word may be readily indexed up to its third letter, the book or cards of a card index or ledger being conveniently arranged for reference. Still another object is to arrange figures on the leaves or cards so that the user can quickly turn to the page or card of the desired number.

### Hardware and Tools.

HAMES FASTENING DEVICE.—J. W. Gowen, Chattanooga, Tenn. The main object of the present invention is the provision of a simple, durable and efficient fastener for collar hames, one in which the adjustment of the hames shall be easy and rapid. It is an improvement on the fastening for hames that consisted most usually heretofore, in a strap passed through loops on the lower end of the hames metal, while the upper end has been drawn together by cinch thongs.

HORSESHOE CALK.—W. F. Abbott, Wilmington, Ohio. Mr. Abbott's invention is an improvement in horseshoe calks, and the object of the inventor is the provision of calks either sharp or dull which may be removed and replaced without disturbing the shoe and without recourse to a skilled mechanic.

### Machines and Mechanical Devices.

BLOWPIPE.—F. L. McGahan, St. Louis, Mo. The blowpipe is of the kind employed in connection with liquid and aeriform fuels, the more particular object being to provide for accurate adjustment in the relative supply of different aeriform bodies, and for causing the admixture of various aeriform bodies to take place thoroughly within the burner.

ROAD GRADING MACHINE.—C. W. Houston, Belle Rive, Ill. Among the principal objects which this invention has in view are: to provide a construction whereby a grader may be controlled to operate over an increased area; to provide a structure wherein the operating angle of the grading blade may be adjusted; and to provide a structure simple and durable.

AIRSHIP.—G. H. Berkka, Seattle, Wash. Primarily this invention has in view a dirigible flying machine of simple and practical construction under easy and positive control of the operator. The machine is of that type which depends on propellers for suspending it in the air and is more especially designed for carrying the operator only.

DRILL.—J. J. Tye, Rochester, Texas. The invention relates to well-drilling machines and is intended to provide various improvements in the manner of actuating the drill rope and controlling the general operations of the machine. It includes novel means for throwing into or out of gear the power operating mechanism and instantaneously bringing the parts into position for operating the drive shaft by means of a hand wheel provided thereon.

CAN FEEDING AND DELIVERING MECHANISM.—J. W. White, Kansas City, Kan. Generally speaking, the invention consists of a chute, can-filling mechanism connected to the chute, a rotatable table, can-feeding means connected to the table, sliding carriages on the table adapted to remove cans from the chute and so place them on the table that they will be located in communicating relation with said feeding means connecting to the table.

### Prime Movers and Their Accessories.

ENGINE GOVERNOR.—I. F. Hunt, Somerset, Ky. The object here is to provide an efficient governor for engines of various types by means of which the flow of motive fluid such as steam, compressed air, water or gas to the engine can be controlled, in which the governor itself can be employed to start the engine, which is positive in its action, and which controls the passage of motive fluid to the engine with certainty. Mr. Hunt has used this governor in his shops and on several neighboring saw mill engines where they have given results superior, he claims, to old style standard governors.

### Railways and Their Accessories.

RAILWAY TIE AND CLAMP.—A. M. Wagner, Pendleton, Ind. The aim in this patent is to produce a tie adapted to be formed of metal and provided with means for supporting and clamping the rail. The special aim is to provide a construction having few parts and to provide also for giving the rail a certain amount of desirable resiliency under a passing load.

RAILWAY CROSSING.—E. McKee and B. H. Tolbert, Ashley, Ill. One of the objects of the invention is to provide a simple device which may be automatically operated by the moving train itself or which may be operated by hand as from a switch tower or other convenient place as desired for closing the transverse slot so that the wheels of the train may have a continuous bearing surface.

RAIL JOINT.—C. E. Dixon, Selma, and W. W. McCrae and J. E. McCrae, Birmingham, Ala. In the present patent the invention is in rail joints. The joint is arranged to be very strong, firm and safe, and will be practically noiseless, insuring smooth running of the rolling stock and eliminating jar, thus adding to the comfort of the traveler and also to the life of the rail and the road bed.

### Pertaining to Recreation.

CARD DEALING MACHINE.—R. A. Bragon, New York, N. Y. The aim in this case is to provide a machine arranged to permit accurate and quick dealing of the cards one by one without the cards being handled or touched by the dealer, thus preventing cheating, and as the cards are not touched by the dealer, soiling thereof by wet fingers is prevented, thus keeping the cards in a sanitary condition.

INCLINED RAILWAY.—A. E. Smith and A. T. Smith, Longbeach, Cal. The intention here is to provide a railway for use in pleasure resorts, exhibitions and like places, and arranged to provide a continuous track for a suspended car to travel on, the track having an up-track, a spiral down-track, and a return track with the lower or starting end of the up-track.

### Pertaining to Vehicles.

SECURING DEVICE FOR WAGON END-GATES.—L. Hillan, Wentworth, S. D. The purpose of this inventor is to provide a securing device for the cross bolt that holds an end gate in place, enabling the instant release of the threaded end of the cross bolt for its removal and also for quickly effecting an attachment of the nut that engages the said end of the bolt.

DEMOUNTABLE RIM.—E. J. Bussey, New York, N. Y. The improvement pertains to wheels for automobiles and other vehicles, and the aim is to furnish a demountable rim, arranged to permit quick and convenient removal and with it the inflatable tire, and replacing of the rim by another whenever it is desired.

FOLDING GO-CART.—M. Folgaman and A. Kraus, New York, N. Y. The invention has for its purpose to provide a cart in which the wheels, springs, hood and other similar parts may be folded in the body which may be so closed that it will resemble a dress-suit case, means being provided to secure releasably the wheels, springs, hood, etc., in operative position.

### Designs.

DESIGN FOR A COVERED DISH.—L. Bouquart, New York, N. Y. In this design for a covered dish the ornamental effect is produced in a body formation of dish that tapers down from the top to a flanged and footed base. The cover lines correspond with those of the body portion and converge at the cap or lifter. Handles are placed at each end of the dish.

DESIGN FOR A HAT PIN.—H. W. Schrader, New York, N. Y. The design includes the usual long and pointed pin and at its head is a ball of relatively small circumference. From the ball hangs a pear-shaped and exquisitely designed drop many sizes larger than the head of the pin.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending April 26, 1910,**

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Acetylene generator and torch, A. F. Jenkins 956,358
Acetylene generator and torch, A. F. J. Johnson (by judicial change of name now A. F. Jenkins) 956,359
Acid concentrating and purifying sludge, Blucher & Satonel 956,276
Acid from acid sludge, obtaining sulphurous, Schillinger & Condran 956,184
Advertising apparatus, J. J. Sharper 956,306
Advertising device, J. A. McCoy 956,142
Advertising machine, M. Rothschild 956,415
Agitator, E. A. Mitchell 955,078
Air brake, combined automatic and straight, W. A. Turner 956,314
Air brake or train pipe valve, A. Olsson 956,153
Air purifying and distributing apparatus, W. H. Fetrick 956,139
Airship built with temporarily removable roof, N. Rachen 956,428
Alarm. See Burglar alarm.
Alarm for indicating life in buried persons, A. M. Bartholomew 956,304
Alkaline chlorids, purifying, C. H. Dasher 956,161
Amalgamator, F. Sthren 956,222
Amusement apparatus, A. A. Welsh 956,243
Amusement apparatus, M. D. Ferguson 956,498
Angle guard, R. F. Humbert 956,100
Animal trap, E. H. McAleer 956,138
Annealing furnace, metal, M. Pedersen 955,989
Anti rail creeper, Ford & Wasman 956,327
Anvil, hook, A. A. Hailley 956,023
Armature casing, B. Whelchel 956,461
Armor, waterproof, A. Siboid 956,208
Ash hoisting apparatus, sidewalk, A. Smith 955,922
Ash lifter, Gangswere & Romig 955,869
Atomizer, J. R. Ballentine 955,987, 956,126
Atomizer, pocket, F. C. Dorment 956,052
Automobiles, supplemental spring for, B. D. Bishop 956,038
Axle, differential railway, B. B. Seabrook 956,195
Axle lubricator, vehicle, M. L. Clamner 956,260
Baby exerciser or jumper, C. F. Emerick 955,954
Bag fastener, H. D. Earl 956,055
Ball, detachable, E. Hickey 956,349
Bearing, roller, G. A. Carter 955,849
Bearing with combined thrust and bearing rolls, roller, O. B. Lockwood 955,888
Bed, A. L. Haley 956,890
Bed, cot, C. H. Young 956,018
Bed, folding, L. Stern 956,219
Bed, sofa, J. Schwensen 956,120
Bell, electrically operated, A. G. Wilson 956,250
Belt loop, F. O. Reinhardt 955,996
Binder, loose leaf, T. Brasil Dinero 956,278
Bit. See Bridle bit.
Boat, auto drive, J. W. Freeman 956,401
Boat, hydroplane, W. H. Fauber 956,467
Bobbin, M. A. Bland 956,277
Body supported bracket, N. J. Birdwell 956,274
Boiler tube cleaner, R. W. Hamann 955,870, 955,871
Boiler tubes, apparatus for heading or turning over, H. B. A. Gullen 956,184
Boiler tubes, device for tightening damaged, C. F. H. Dittmann 956,311
Boilers, pressure reducing device for high-pressure, J. C. Ulrich 956,077
Bottle attachment, V. Kicevich 956,402
Bottle closing apparatus, C. W. F. Meuerschmidt 955,891
Bottle filling machine, J. H. Champ 956,288, 956,289
Bottle, non-refillable, J. Stephen 955,919
Bottle or receptacle, vacuum, J. B. Miller 956,395
Bottle, siphon, F. Spitzenberg 956,442
Bottle washing apparatus, O. Bich 956,088
Box, F. Jager 956,380
Brake, C. W. Aveling 956,265
Brake-applying mechanism, Conniff & Burgess 956,258
Brake beam, P. B. Harriman 956,067
Brake lever strut or post, C. H. Williams, Jr. 956,349
Brick drying apparatus, W. R. Martin 956,128
Brick handling machine, R. J. Fritsch 956,320
Bridle bit, Finnel & Carson 956,088
Brush having sponge surface, fountain bath, B. D. Knickerbocker 956,108
Brushing and polishing machine, shoe, J. A. Brewer 956,041
Bucket, clam shell, E. Murrey 956,137
Buckle, A. Nordlund 956,139
Building construction, bond plate for, B. S. Heller 955,847
Bundle wiring machine, T. Magnus 956,387
Burglar alarm, J. G. Payton 956,160
Burglar alarm, E. Critchfield 956,288
Burglar alarm, C. C. Hamlett 956,414
Burner, S. C. Hix 956,094
Burner, A. T. Still 956,228
Butter cutting tool, C. Glaus 956,072
Cableway apparatus, A. N. Norris 956,159
Cager, automatic, B. C. Buxton 956,097
Cages, catching devices for, H. W. Seifrian 956,214
Caisson construction, O. Merritt 956,189
Can body machine, F. Rudolphi 956,180
Can body making machine, F. Rudolphi 956,179
Can feeding apparatus, R. M. Burr 956,008
Candlestick, F. J. Primaveri 955,992
Cane and musical instrument, combined, H. Pinelli 956,304
Car controller, street, J. H. Huey 956,383
Car door, grain, E. M. Greenfield 956,078
Car door lock, A. O. Bucklin, Jr. 956,281
Car door, mining, J. S. Foster 956,320
Car fender, J. Blackburn 956,479
Car fender, W. P. Clampitt 956,488
Car frame, steel, A. Christianson 955,860
Car hauls, feeder for, Jordan & Pemberton 955,884
Car, poultry, F. X. Mudd 956,401
Car safety wheel, railway, J. T. Andrew 956,261
Car vestibule door, J. S. Muckle 956,580
Carbureter, R. J. Ennis 955,986
Carbureting apparatus, R. C. Dawson 956,048
Carpet fastening, C. F. Craig 955,888
Carpet sweeper handle attachment, J. M. Spangler 956,215
Cart, hoisting, N. Slavin 956,208
Carton folding and gluing machine, F. J. I. Kuhlmann 956,108
Cartridge shell, H. M. & L. A. Sherman 956,201
Cattle guard, L. T. Cox 956,298
Chain fastener, R. A. Bickamp 955,842
Chain guide for pull sockets, H. Hubbell 956,364
Chains, joining link for, G. E. Scott 956,192
Chart and templet, dress, S. Komura 956,370
Check displayer and annunciator, W. F. Schwalger 956,485
Churn, M. P. Winders 956,030
Churn and butter worker combined, R. B. Disbrow 956,310
Cigar protector, F. Buckmann 955,900
Cigars with hollow tips, making, A. Barr 956,022
Circuit closer, Tansley & Hillman 956,118
Clarifier and filter, centrifugal, T. B. Marshall 955,890
Coal crushers, detachable runner for, J. E. Hornlmayer 956,352
Closet seat, T. G. Philpot 956,416
Clothes line support, J. Hrimo 956,079
Clutch, magnetic, A. Pick 956,164
Coat, D. Warren 956,238
Coat and pants hanger, S. Itkbman 956,501
Coin controlled indicator, W. H. Kings 955,889
Coke quenching machine, Mitchell & McCreary 956,097
Combination wrench, H. E. Anderson 956,407
Concentrator, H. L. Black 956,024
Concrete pipes, machine for making, W. A. Shelton 956,200
Concrete, reinforced, W. F. Scoll 956,194
Concrete structures, device for fastening to, H. D. & W. D. Emmons 956,059
Concrete walls, skeleton structure for, H. Bout 956,424
Condenser, I. J. Snow 956,210
Condenser, steam, I. J. Snow 956,211
Conveyers, intake for pneumatic, J. W. East 955,952
Copper ore concentrates preparatory for smelting, agglomerating or briquetting, T. Rouse 955,909
Core for molds, expansible, P. C. Merillat 956,135
Corn popper, Stine & Montz 956,224
Corner bead clip, H. D. King 956,384
Corner beads or strips, clip for, J. M. Shear 956,480
Counter holder, C. E. Haney 955,895
Coupling, B. T. Greenfield 956,076, 956,077
Crutch tip, B. H. Seibert 956,438
Cultivating implement, F. P. Burdge 956,477
Cultivator, W. L. Morford 956,152
Curtain fastener clamp, M. L. Thomas 956,446
Curtain fixture, J. Schoepe 956,482
Cuspidor, J. Orsang 956,407
Cuspidor, L. Herrath 956,402
Cycle pedal, H. I. Francis 955,867
Dam and apparatus for constructing the same, H. L. Cooper 955,861
Davit for ships' boats and similar purposes, S. L. M. Sivard 956,204
Delivery mechanism, W. Scott 956,193
Desiccating apparatus, J. R. & C. H. Campbell 956,038
Die, H. M. Schwartz 956,434
Display fixture, W. E. Taylor 956,445
Display folder, M. H. Wilson 956,252
Distilling coal, H. Koppers 956,371
Door closer and check, C. B. Bishop 956,275
Door handle, safety, Schuyler & Laughlin 956,428
Door hanger, H. E. Ballard 956,025
Door lock, J. W. Phelis 956,162
Door opener, electric, J. Loch 956,379
Door screen, ventilating, I. B. Seeley 956,437
Drawing rack, W. R. Willis, Jr. 956,013
Drawing table, adjustable, A. Hoffman 956,096
Dredging scoop, T. S. Barwis 956,089
Drill. See Pneumatic drill.
Drill cuttings, means for collecting, M. L. Sargent 956,181
Drinking fountain, R. Kaminsky 955,880
Drying machine, J. P. Marshall 956,129
Dust collector, G. A. Bauer 956,270
Dust guard, L. Y. Williams 956,012
Dust receptacle, J. S. Thurman 956,480
Dye and making saline blue vat, R. Herz 956,348
Dyeing machine, J. T. Pearait 955,980
Eaves trough, self cleaning, H. Krentzberg 956,078
Electric and hand power elevator, self-sustaining, T. Wright 955,982
Electric conductor, armored, P. Schroder 956,188
Electric cut-out, T. B. Murray 956,133
Electric generating system, automatic, M. A. Newstetter 955,904 to 955,906
Electric light hanger, White & Flowers 956,345
Electrical distribution system, A. S. Hubbard 956,353
Electrical space communication, G. W. Pickard 956,165
Embossing press, O. McCann 956,140
Engine igniter, gas, G. Gray 956,075
Engine installation, combined reciprocating and turbine, J. Irving 956,367
Engine stop, automatic, H. C. Locke 956,380
Engines, device for controlling power of explosive, J. H. Schoop 955,916
Engines, timer for combustion, P. B. Fant 955,864
Engraving machine, R. Getzert 956,329
Envelope, double, A. E. Harker 956,345
Evaporation and apparatus therefor, method of, N. H. Hiller 955,985
Excavator power, J. B. Webber, Jr., reissue 13,107
Excelsior machine, B. D. Misner 956,130
Exerciser, R. F. Bailey 956,324
Eyeglass mounting, F. A. Stevens 956,380

(Continued on page 384.)

## THE HEAVENS IN MAY.

(Concluded from page 378.)

telescopes of sufficient size to pick up the faint greenish disk of the planet.

The moon is in her last quarter at 8 A. M on the 2nd, and is new at midnight on the 8th (during the solar eclipse visible in Australia) She reaches her first quarter at 9 P M on the 15th, is full during her eclipse on the night of the 23rd, and comes to the last quarter again at 5 P M on the 31st. She is nearest us on the 8th, and farthest away on the 21st.

During her circuit of the sky she passes close to Venus on the 5th (and likewise near the comet the same afternoon), to Saturn on the 7th, Mercury on the 10th, Mars on the 12th (pretty close), Neptune on the 13th, Jupiter on the 19th, and Uranus on the 28th

Princeton University Observatory.

## NATURE AS AN INVENTOR.

(Continued from page 379)

use Those admirable workers in skin, the Kaffirs and Eskimos, employ only knives. The idea of the knife edge in combination with the leverage afforded by tools of the grasping type had never occurred to them Yet shears are exemplified by the jaws of many insects, as well as by those of tortoises and turtles

Only of comparatively recent years has man made boxes in which to store money, trinkets, or other valuables Yet Nature has had her boxes from time immemorial Some of the most interesting of these take the form of seed-pods as, for example the stout casket in which Brazil nuts are packed In this instance, too, the primitive idea of the puzzle—later elaborated by the Chinese, as well as by other races of mankind—seems to lie dormant, for here we have a vast number of nuts, so cleverly packed into their pod or casket, that if once they are taken out it is almost impossible for human hands to restore them to their place

The hinge as attached to a lid or door, has been known to man only for centuries, yet Nature has made use of it literally for billions of years. In proof of this statement, it is only necessary to indicate a bivalve shell, such as an oyster or a clam We know from geologists that such shells are among the earliest indications of life upon this earth with which they are acquainted The eggs of many insects, too, open with a very perfect little hinge, while the little lid which covers the cunningly contrived nest of the trap-door spider, is also hinged in a most ingenious manner by means of silken bands

Savage man had no means of preserving light for himself after the setting of the sun, and it was only with the slow progress of civilization that he became inspired with the idea of artificial illumination Yet this was not for want of examples set by Nature, for many animals carry about with them bright lights during the hours of darkness. Marine organisms, in particular, emit phosphorescent radiance, while many kinds of insects, to which such names as glow worms, fireflies or lantern-flies have been applied, are highly luminous. In many instances the precise manner in which the light of these creatures is produced has baffled scientific inquiry Still, the fact remains that Nature had her living glow lamps ages before man emulated her example

Formerly the surgical operation known as cupping was so constantly performed that scarcely any man attained middle age without undergoing it. The object in view was the removal of blood from some definite spot; the surgeon, by means of his apparatus, calling atmospheric pressure to his aid. Man might very well have invented this operation after examining the numerous suckers which stud the long arms, or tendrils, of an octopus. The principle involved is identical in each case. Indeed, many of man's most useful inventions depend for their efficiency upon the weight of the atmosphere and the creation of a more or less perfect vacuum Like the old fashioned cupping glass the well known toy known as the 'sucker,' reminds us of the octopus By means of the sucker—a small circle of moist leather with a string attached—large stones may be lifted in exactly the same manner that the octopus dislodges rocks or holds down its struggling prey That comparatively modern invention the pneumatic peg is an almost identical device The apex of the peg is fitted with a sort of a cup made of India rubber When this is pressed upon a smooth flat surface, such as a pane of glass the air is forced out of the cup and a vacuum formed The pressure of the atmosphere then causes the cup to adhere to the glass with sufficient force to enable objects to be suspended from the peg Further the man who had studied the octopus might have added to the inventions already enumerated, that of the common pump, which raises water simply by the action of the atmosphere

That well-known device, the ball-and-socket joint without which many of our instruments and tools would be clumsy and impracticable, has many prototypes in Nature Perhaps the most familiar of these is seen in the articulation of the human shoulder bones—or, indeed in the bones of many animals for the marvelous flexibility of the snake is rendered possible only because the vertebræ of this reptile constitute a long chain of balls and sockets beautifully adjusted one to the other Another very perfect example of ball-and-socket movement is found in the case of the sea urchin Each of the spines with which the shell of this creature is covered is swollen at the base into a cup-like form and this cup fits accurately upon a little rounded prominence of the shell, which exactly fits into the cup just as the ball of the human thigh bone fits into the acetabulum The legs of insects in their articulation to the body supply examples of the ball-and socket principle too numerous to mention

The idea of the flask or bottle is eminently natural—i e it has played a part in the economy of Nature from time immemorial Perhaps the most remarkable examples are to be found in the vegetable kingdom among the plants known as gourds, the seed vessels of which assume forms calculated to remind the least imaginative individual of antique pottery

We have already seen that the theory of the common pump might have formulated itself in the mind of man after he had studied the habits and structure of the octopus There is moreover a prototype in Nature for that far more complicated device known as the force-pump This prototype is the human heart Anatomists agree that it is constructed on principles which are marvelously up-to-date In an incredibly short period the whole of the blood in the human body passes to the heart and is driven from it again with a force which carries the stream to the tips of the fingers and toes, while as everyone knows the action of the heart persists, night and day, throughout the whole life of a man If we regard the heart as the prototype of force-pump wrought in metal by the hands of mankind we must still be impressed by its immeasurable superiority its renovation and repairs are affected while the mechanism is in rapid motion

The simplest form of sewing is that which is in vogue among such primitive races as the Eskimos and Kaffirs It consists in boring holes through the material which is to be joined together and pushing the thread through them The reader will observe that the operation is of so rough-and ready a character that no needle is required, and one is almost tempted to imagine that mankind might actually have copied this method of sewing from having observed the manner in which the tailor bird constructs its nest Be this as it may, the fact remains that this bird actually sews leaves together by their edges, and makes its nest within

the pocket like receptacle thus formed. Its method of working resembles exactly that which has been detailed above First the sharp-pointed beak is used to form a slit or hole in the leaf, and through this a piece of tough grass, or other vegetable fiber, is passed A second hole is made and the natural "thread" is drawn through it, and so on until the work is completed by a tucking in and adjustment of unruly ends Should the reader care to visit a museum, and make a mental comparison of stitches made by savage tribes and those formed by the tailor bird, he will frequently discover that the latter are far less clumsy than the former In a word it may be asserted without fear of contradiction that mankind was not first in the field where the art of needlework is concerned The sewn seam is another of Nature's own contrivances

The arts of spinning and weaving have also their prototypes in Nature The majority of nest-building birds exhibit a more or less strongly marked weaving instinct. This instinct is most strongly developed in the case of a genus of finch-like birds indigenous to the warmer parts of Asia and Africa The spinning of fine threads so as to form thicker strands and the combination of these into webs, are operations characteristic of many insects and their allies Many spiders, as everyone knows, construct silken webs which they employ as a means of capturing their prey, or of protecting their egg-clusters from injury But it is among insects of the sub-order *Heterocera* (i e the moths) that the spinning of silk has been brought to the highest state of perfection Moths, indeed, may with justice be termed the first spinners—the inventors under the guiding hand of Nature of this invaluable art. Take, for example, the cocoon of the well-known Cecropia moth—the so-called American silkworm It is entirely constructed of silk, which is secreted by glands in the mouth of the grub or caterpillar As soon as the insect has become full-fed, and is about to pupate, it sets about the formation of its cocoon and labors unceasingly until it is completed The exact method of construction is so intricate that considerations of space forbid us to describe it in detail. Suffice it to say that the caterpillar first constructs of silken threads a kind of scaffolding, or framework, and then—laboring from within—goes to and fro about the skeleton structure depositing its endless silken thread by means of a figure of eight movement of its head In this way a kind of tent of marvelous toughness is built up, wherein the caterpillar changes to a chrysalis and passes safely through the quiescent period of its existence, to emerge eventually as an adult moth

In passing, the reader may be reminded that many kinds of caterpillars contrive a kind of trap at the month of their cocoons similar in principle to those made by man for the capture of crabs, lobsters, and eels Within the neck of the Emperor Moth's cocoon, for example, there is a conical arrangement of stout, bristly appendages which form a well-nigh impenetrable barrier against the attacks of enemies which may attempt to force an entrance from without Yet owing to the flexibility of these appendages, the fully developed moth can push its way out of the cocoon with perfect ease If the reader has followed this description carefully, he will perceive that the trap of a moth's cocoon is a veritable reversed counterpart of the familiar lobster-pot—a device which is employed by fishermen in many parts of the world

The writer is not aware whether Nature's contrivance of a box that cannot roll off a shelf has ever been put to practical use by mankind It is obvious, however, that such a device might very well form the basis of more than one valuable invention The principle may be studied by all those who are able to visit the rocky ledges used by sea fowl as breeding places—or, indeed, by those

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES.

CORRESPONDENCE with a reliable manufacturing concern, equipped to manufacture remote control switch is solicited. F T McNally, Mandan, North Dakota.

Inquiry No. 9018.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

## PATENTS FOR SALE.

FOR SALE.—Patent No. [illegible]. Mixing mechanism. A simple novel structure. Can be cheaply constructed. A household necessity. Price moderate. Address Frank P Lynch, McConnellsburg, Pa.

Inquiry No. 9007.—Wanted, the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

## FOR SALE

FOR SALE.—Models and molds for everything in plaster, iron and bronze. Cutting outfits, drophammers and dies. Acorn Works, Indianapolis, Ind.

Inquiry No. 9014.—For manufacturers of machinery, supplies, etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

HOUSE Wife's Twentieth Century Delight. Article in hardware which can be manufactured for 10 cents, its simple construction, magic operating features and pleasing appearance will create a demand which will prove a fortune. Will sell outright or be interested in propositions of manufacturing on royal basis. S. H. Kelly, Wellington, Texas.

Inquiry No. 9019.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York

Inquiry No. 9023.—Wanted, to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

## HELP WANTED.

WANTED.—A high class superintendent on track revision work, raising and lowering grades. Only those with experience need apply. Experience, Box 773, N Y

Inquiry No. 9029.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

## SITUATIONS WANTED.

MACHINE SHOP FOREMAN, 25 years' experience in U S and foreign countries 11 years as foreman, seeks similar position. First class references. For further particulars address Foreman, Box 773, N Y

Inquiry No. 9038.—Wanted, the address of the Chipman Electric Purifying Co.

## MISCELLANEOUS.

CHEMICAL analysis, investigation and research work. Processes devised. Correspondence invited. J F Danziger, Chemist, Milburn, N J

Inquiry No. 9043.—Wanted the address of Farney Safety Razor Co.

## SALE AND EXCHANGE.

FOR SALE.—Engine lathe. Our regular $75.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $42.50. L F Grammes & Sons, Allentown, Pa.

Inquiry No. 9052.—Wanted, address of firms who install plants to manufacture nitrogen.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9055.—Wanted, address of parties interested in Egg Cleaning Machines.

Inquiry No. 9060.—Wanted to buy machinery to manufacture seed corn racks.

Inquiry No. 9066.—Wanted complete outfit for export for making rice-flakes and wheat-flakes.

Inquiry No. 9073.—Wanted, machinery to manufacture cocoanut oil; also the crude material.

Inquiry No. 9074.—Wanted, to buy old model locomotives or steamboats, such as were exhibited with nickel-in-the-slot attachments in ferry houses, etc.

Inquiry No. 9075.—Wanted, to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted, the address of parties in Canada who could make a safety razor.

Inquiry No. 9077.—Wanted, the address of manufacturers that make small articles of wood, such as checker boards, etc.

Inquiry No. 9078.—Wanted, the address of manufacturers of sewer pipe, made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9082.—Wanted, the address of firms manufacturing small beer brewing plants, from 15 to 25 gallons a day.

Inquiry No. 9085.—Wanted, to buy longitudinal hollow perforated tubing.

Inquiry No. 9088.—Wanted, to buy a pine wood [illegible].

Inquiry No. 9090.—Wanted manufacturers of [illegible] and [illegible] supplies, also patent adjustable bachelor buttons.

Inquiry No. 9092.—Wanted, the address of some firms who manufacture permanent lamp wicks.

Inquiry No. 9094.—Wanted address of The [illegible] Aythmometer Company, also [illegible] Arithmometer Company.

Inquiry No. 9095.—Wanted, name and address of the manufacturers of the duplex revolving pencil sharpener.

Inquiry No. 9096.—Wanted, the address of manufacturers of spiral welded pipes, possessing great strength.

Inquiry No. 9097.—Wanted, address of makers of [illegible] Water Wheels.

Inquiry No. 9098.—Wanted, name and address of the manufacturers of the aerator.

Inquiry No. 9099.—Wanted, address of manufacturers of machinery for making wire cables.

Inquiry No. 9101.—Wanted, addresses of manufacturers of a dip or magnetic needle, for exploring for iron ore.

Inquiry No. 9104.—Wanted, addresses of manufacturers under the name of A. G. Co. Standard.

Inquiry No. 9107.—Wanted, addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

Inquiry No. 9109.—Wanted addresses of the manufacturers of the Dux Desk Clock.

Inquiry No. 9110.—Wanted to buy machinery for reducing old tin cans, so that they may become a source of revenue.

Inquiry No. 9113.—Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

Inquiry No. 9114.—Wanted name and address of manufacturer of the Auto Lantern Globe. Fits all lanterns.

Inquiry No. 9116.—Wanted a machine for making pen nibs, similar to Wm. Mitchell's G & J nibs and Waverly nibs.

Inquiry No. 9117.—Wanted names and addresses of the manufacturers of pedometers.

Inquiry No. 9118.—Wanted, a muffler for a gasoline engine, built upon the principle of the Maxim silencer, recently brought out for use on rifles.

Inquiry No. 9119.—Wanted, name and address of the manufacturer of Berlin bullet proof cloth.

Inquiry No. 9120.—Wanted, the address of the Ideal Fuel Feeder Co.

Inquiry No. 9121.—Wanted manufacturers of cut stencils for fancy work, sofa pillows, etc. and oil colors and brushes for same.

Inquiry No. 9124.—Wanted, name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

Inquiry No. 9127.—Wanted, address of L. Dermigny manufacturer of a family ice machine for $10.00.

Inquiry No. 9131.—Wanted, information as to how or where I could get a sample of tin ore.

Inquiry No. 9132.—Wanted, manufacturers of a gasoline traction engine with a hoisting attachment; in other words, the machine will be used as a portable stump puller to pull sassafras roots, used in making oil of sassafras.

Inquiry No. 9134.—Wanted, a small hydraulic motor, capable of giving about one horse power with a water power of 25 lbs. per square inch.

Inquiry No. 9135.—Wanted, name and address of manufacturers of the Parshall Compressed Air Ice Machine.

Inquiry No. 9136.—Wanted, the name and address of a skunk raising farm.

Inquiry No. 9137.—Wanted, a device that will braid leather strips for horse whips.

Inquiry No. 9138.—Wanted, the address of manufacturers of machines capable of forming a number (12 or more) of pieces of paste about 25 mm. x 25 mm. x 6 mm., made of lead oxide and sulphuric acid, and placing them into a frame having a separate compartment for each piece, the space between each piece and the next being all round 4 mm. The process could be somewhat similar to biscuit making.

Inquiry No. 9139.—Wanted the name and address of some manufacturer of a coffee mill run by water motor.

Inquiry No. 9140.—Wanted, manufacturers of disc records for gramophones that use a sapphire point instead of a steel needle.

Inquiry No. 9142.—Wanted, an appliance used in ice chests to make ice last longer.

Inquiry No. 9143.—Wanted, name and address of the manufacturers of an air mattress.

Inquiry No. 9144.—Wanted, manufacturers of machinery for making soda water tubes, commonly known as straws.

Inquiry No. 9145.—Wanted, to buy machinery to load blasting caps or detonators.

Inquiry No. 9146.—Wanted, address of firms engaged in die cast work.

Inquiry No. 9147.—Wanted manufacturers of machinery for making manila rope and all kinds of ropes from fibre of century plants, such as maguey agave, henequen, maguey or any such fibres.

Inquiry No. 9148.—Wanted manufacturers of machinery for weaving bags of fibre, also manufacturers of machinery for separating fibres as above mentioned from their respective plants.

Inquiry No. 9149.—Wanted, manufacturers of machinery for roasting coffee for small and large industries.

Inquiry No. 9150.—Wanted, manufacturers of machinery for the manufacture of French heels for ladies' shoes.

Inquiry No. 9151.—Wanted, manufacturers of cocoanut oil machinery.

Inquiry No. 9154.—Wanted, the address of the [illegible] Safety Lamp Filler and Ventilator.

Gas, Gasoline and Oil Engines

Including Producer Gas Plants

By GARDNER D. HISCOX, M.E.

*Eighteenth Edition, Revised, Enlarged and Reset. Size 6½ x 9½ inches. 476 pages. 412 illustrations. Price $2 50 postpaid*

THIS new revised and enlarged edition is a complete, comprehensive and thoroughly up-to-date work, treating fully on the construction, installation, operation and maintenance of gas, gasoline, kerosene and crude petroleum engines.

It treats on the theory of gas, gasoline and oil engines as designed and manufactured in the United States, for stationary, marine and vehicle power, together with their care and running.

Electric ignition by induction coil and jump spark are fully explained and illustrated. Valuable information on the testing for economy and power, and the erection of power plants is also included. The special information on producer and suction gases cannot fail to prove of value to all interested in the generation of producer gas and its utilization in gas engines. A list of the leading gas and oil engine manufacturers in the United States and Canada, with their addresses, is included, as well as a list of United States patents issued on gas, gasoline and oil engines and their adjuncts from 1875 to date.

(Continued from page 385.)

who care to experiment with the eggs of these birds on an ordinary shelf or table If one sets a fowl's egg rolling on a table, the odds are in favor of its falling to the ground Not so however, with the eggs of ledge-frequenting sea birds For the forms of these eggs are designed so carefully by Nature, that it is virtually impossible to impart to them any but a circular movement. If disturbed these eggs roll round and round until the impetus given to them is expended It is scarcely necessary to dilate upon the importance of this device inasmuch as such eggs, being laid on the narrow ledges of perpendicular rocks would--but for their peculiar form--be precipitated into the sea upon the slightest movement of the parent bird As it is careful observers have stated that although there is a constant coming and going among the birds and a constant rotation on the part of the eggs not one of the latter is dislodged

The stings and mouth parts of insects typify in many ways the devices and inventions of man The sting of a bee or a wasp might well have been taken as a model of the modern hypodermic syringe, so too, might the elaborate arrangement of blades and saws by means of which the female mosquito makes and enlarges her puncture The instruments, fitted together and working in unison, form a tube through which the insect sucks the blood from her victim and incidentally inoculates him with malarial fever The several parts of this instrument are shown modeled on a greatly magnified scale in the accompanying photograph The fact that the sharp blades, tools and saws lie within a sheath when not actually in use is of especial interest, for herein we see typified the sheath or scabbard by means of which mankind protects the keenness of his edged tools and weapons A still more perfect type of the hypodermic syringe is the fang of a poisonous snake When the reptile makes its stroke, the base of the fang is driven against a reservoir with the result that the liquid poison is driven through the tubular fang and forced into the wound Even in the case of large snakes, these deadly weapons are surprisingly slender and delicate, so that the wounds made by them would be quite inconsiderable were it not for the fact that a deadly liquid is injected—exactly as is the case with the hypodermic syringe

There are many natural devices by means of which plants and animals travel through the air and mankind is at present engaged in a close study of these with a view to perfecting his own air ships and flying machines The creatures whose appearance and habits resemble balloons most closely are the so-called globe fishes of tropical seas For the most part their bodies are covered with strong spines, or at least with hard plates, but the strangest characteristic of these ocean dwellers is their power of dilating the gullet with air, when the body swells out into a globe-like form and the spines are erected, furnishing a formidable protection When so inflated, globe fish are unable to swim They drift about upon the surface with the underside turned upward, and skim over the waves impelled by the passing breeze It cannot be doubted that this singular habit reminiscent of the balloon is beneficial to these fish in that it enables them to escape the onslaught of sharks and allied carnivorous creatures of the deep

In conclusion, we may glance for a moment at Nature's own electric batteries—two remarkable examples of the capacity of animal structure to produce electricity to store it so to speak, and to discharge it at will Both these creatures are fish one belonging to the eel tribe, the other being a species of ray known as the torpedo fish As a matter of fact the torpedo rays belong to several species which are met with in the Atlan

tic, Mediterranean and Indian Oceans. The broad, smooth body has a rounded outline, and on each side of the head there is an electric organ capable of giving electric shocks. The accompanying illustration shows one of these fish dissected to show the seat of its electric power. On the left, the nerves supplying the organ are dissected away. The prismatic areas on the surface of the organ indicate the vertical columns of electrical plates, of which there may be 500,000 in each organ. The arrangement of these plates, or disks, is like the metallic portions of the voltaic pile while each is separated from its neighbor by a delicate membrane, which takes the place of the cloth. The object of this electric power on the part of the torpedo ray appears to be to enable the creature to secure its prey either by killing it, or rendering it temporarily insensible. It is said that just before the shock is delivered, the eyes are depressed in the head like those of a toad when swallowing a large insect.

The electric eel of Southern America sometimes attains a length of six feet, and its electric organs are proportionately four times as large as those of the torpedo. When about to deliver its shock it points its body in the direction of the intended victim, stiffens itself and with a sort of shudder, the electric fluid is emitted. It is said that the fish which is the object of the discharge rarely or never escapes but simultaneously with the shudder of the eel turns on its back and lies motionless—an easy prey to the electric monster.

It would be possible to dilate at much greater length upon the natural prototypes of human inventions. Enough has been penned, however, to show how frequently man's thoughts reflect the devices which already exist in organic nature. The moral to this should not be far to seek. If so many existing human inventions have been anticipated by Nature, we may conclude that with Nature lie the secrets of inventions yet to come, nor can it be doubted that a close study of animal and plant life will from time to time bear fruit in the form of mechanical devices which will prove of inestimable value to mankind at large. For this reason, if for no other, the inculcation of Nature study in the minds of young people is highly desirable.

---

### THE NICE AVIATION MEET.

(Concluded from page 372.)

made but one stop, at Litchfield. He started readily from that place at 4:09 A. M. and covered the remaining 68 miles in 1 hour and 21 minutes beating the train that accompanied him. The last 24 miles were flown in 24 minutes on account of a favorable wind. Eight thousand people are reported to have watched him arrive and to have given him a rousing welcome.

Next to the Blériot Latham race across the English Channel last July, this cross-country flight is the greatest achievement so far in aviation. In the light of what has already been accomplished it would seem that from 800- to 1,000-mile flights without a stop for fuel are now quite possible of accomplishment, the only limiting factor being human endurance. In both his attempts at flying from London to Manchester Grahame White was obliged to give up on account of the great strain undergone by him in maintaining the equilibrium of his biplane in the strong and gusty wind. When some device is provided which will maintain equilibrium automatically, the strain upon the aviator will be greatly relieved and driving an aeroplane will then be no more fatiguing than running an automobile.

---

Siccative powder is prepared by mixing 30 parts of lithopone, 30 of zinc-white and 40 of manganese borate. Pass the whole through a fine sieve. This powder is a good drier for white paints.

NEW YORK, SATURDAY, MAY 14th, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## NEW QUEBEC BRIDGE DESIGN

ACCORDING to a recent dispatch to one of the New York dailies the Quebec Bridge Board after extended investigation has approved a plan for the superstructure of a cantilever bridge to take the place of the one which collapsed several years ago. It is also announced that tenders for construction will be accepted either on this design or on satisfactory alternative designs submitted by bidders. It is stated furthermore that the Dominion government will require not only that the contracting firm accept full responsibility for the project, whether it be constructed on the Board's design or from its own plans, but also that the firm make a very large cash deposit as guarantee of successful completion of the work.

The design now approved by the Commission, says the dispatch, "is that which was sharply criticised a few months ago in an American scientific periodical", and we are informed in this connection that the Canadian government has decided that the criticism then made did not justly apply. We are further told that "the Board, while convinced that the designs will make a safe and satisfactory bridge, is not disposed to close the door to other designs."

Since the SCIENTIFIC AMERICAN is the only journal that has printed the plan of the new design drawn up by the Board and subjected it to extended criticism, we presume that we are the American scientific periodical referred to. The plan and discussion was printed in our issue of February 12th, and our readers will remember that we took exception to the design on the ground that it was not only of inferior merit, considered from the bridge engineer's standpoint, but that if constructed it would be the "ugliest bridge of monumental proportions among those hitherto proposed or built." Objection was also made to the design on the ground that because of its narrow width it would not have sufficient rigidity, the Forth bridge, which is of less span, having a ratio of width to length of 1 to 14, whereas the Quebec bridge would have a ratio of only 1 to 20. We objected further more, to the height of the towers, which in the Board's design is to be only 290 feet as against a height of 315 feet in the bridge which fell at Quebec, and of 330 feet in the Forth bridge. We showed also that the effect of low height and narrow width had been to unduly increase the weight of the structure, the Quebec bridge requiring the enormous average weight of 24 tons of steel (half of it nickel steel) per linear foot, as against a weight of only 10 tons of carbon steel per linear foot in the Forth bridge—an increase out of all proportion to the heavier loading of the proposed Quebec structure.

The value of the Board's decision to invite outside designs depends upon the length of time that is allowed to bidders for the proper preparation of plans for a structure of this great importance. The Board has taken about two years to prepare its own plan, and if outside bidders are to be limited to a few months time it is scarcely likely in view of the heavy penalties imposed that they would be prepared to put in bids which they must perforce have thrown together very hastily. If the competition is to be thrown open to the designers and bridge builders of the United States and Europe, not only should abundance of time be given for the working up of the necessary plans and estimates, but it would be advisable for the Canadian government to arrange for the plans, both of the Quebec Bridge Board and of outside bidders, to be subjected to the award of an independent Board, preferably international in character.

## FUEL ECONOMY AND OUR NATURAL RESOURCES

THE problem of preserving the natural wealth of the country may be attacked from two sides, the legislative and the mechanical. The operation of the first method may be seen in the admirable movement of the Federal government to prevent the ruthless waste of the country's natural resources which results from the improvident methods by which they are gathered from mine, field, and forest. Only posterity will be able to estimate at its full value the recent legislation for the conservation of that natural wealth with which the United States has been so richly endowed.

But after the fostering care of the government has done all that it may to conserve by the prevention of waste, it remains for the consumer to so utilize the raw materials, as to obtain from them the maximum amount of useful output, whether in the form of power or of finished product, with the least possible amount of wastage. This indeed, is one of the most important and attractive objects of effort in the great industrial world. To the engineer of high professional instincts it is not sufficient to do a certain work and do it fairly well, rather, it must be done with as close an approximation to perfection as the conditions of the art will allow.

Economy of performance has been the constant aim of the industrial engineer, particularly in recent years, and from time to time we have recorded in these pages certain successive steps, some of them epoch making in their importance, in this constant endeavor to bring working efficiency into closer approximation to theoretical efficiency. What we have said applies with particular force in the field of steam engineering, in which it may be said that at the last analysis the object of all improvements is to lessen the consumption of fuel for a given amount of work. Fuel economy, moreover, apart from its direct connection with the profit and loss account of any industrial enterprise, has a most important bearing upon the question of the conservation of natural resources. The world's coal supplies are by no means unlimited. The consumption is enormous as it is at present, is increasing at an accelerating rate, and every reduction that is made in the average amount of fuel which must be burned to secure a given amount of work, means that the life of our coal and oil fields is prolonged to exactly that extent.

At the present time there are two important developments which promise to give economical results whose value it would be difficult to overestimate. In both cases they have to do with the transportation of freight in bulk, the one relating to the engines of slow speed cargo boats, the other in the motive power of those huge freight trains which are so characteristic of American railroads.

The reduction in the cost of transporting water borne freight has been made possible, or soon will be, by the successful application of mechanical reduction gear to cargo ships of moderate speed—a problem to which some of the ablest engineers and the most renowned manufacturing firms in the world are now devoting close attention. MacFarland and McAlpine, and Westinghouse, in this country, and the Hon. Charles Parsons in England have independently produced a gear which will enable slow and moderate-speed steam ships to utilize the highly economical fast-running steam turbine for driving slow-speed propellers with a loss of efficiency in the transmission gear of only two per cent. Parsons has gone so far as to test the new installation against the old reciprocating engines, in a cargo ship of 4,500 tons displacement, and he has proved in a series of comparative tests that the cargo ship of the future can be driven at present speeds with a saving in the coal bill of from 17 to 20 per cent. Now since about two thirds of the world's shipping are made up of freight steamers, it can be seen that when some form of this system has been generally applied, as it undoubtedly will be, there will be a great aggregate reduction in the consumption of fuel by the world's merchant marine. For fuller information regarding this epoch making device, reference is made to articles published in the SCIENTIFIC AMERICAN of February 12th and April 23rd of this year.

Equally important are the economies in the transportation of railroad freight which are now rendered possible by the perfection of appliances for the use of superheated steam. Although the application of superheat has been practised for several years in Europe, it is of comparatively recent introduction in this country, but although our engineers have been a little late in taking hold of the problem, they have done such good work that on one of our leading western roads, the Atchison, Topeka and Santa Fe, superheated steam is being used on a number of the largest freight engines with conspicuous success. In a series of tests with two identical compound freight engines running over the same stretch of road under identical conditions, one a 4-cylinder compound using saturated steam, and the other a similar 4-cylinder compound with a superheater of the Jacobs type added, the superheater engine showed a decrease in coal consumption of 19.6 per cent for constant hard working on heavy mountain grades; it gave an average of 11.6 per cent more dry steam per pound of coal than the non-superheater engine, and the boiler and its accessories proved to have a total higher efficiency of 15.8 per cent. These figures were obtained by H. MacFarland, the engineer of tests of the railroad, who explains the remarkable economies secured by the facts: First, that superheated steam of high temperatures behaves somewhat like a gas, it being possible to extract a considerable amount of heat before any condensation takes place, secondly, that for the same cut-off in the cylinder, the weight of steam required is less with superheated than saturated steam of the same pressure, and thirdly, that, as compared with saturated steam superheated steam has greatly reduced thermo-conductivity, and the amount of heat absorbed by the cylinder walls is only a fraction of what it would be were the steam saturated. The details of this system of superheating as applied to locomotives of the Mallet type will be found in an illustrated article published in our issue of January 29th of the present year.

Important as are the economies that have been made possible in the broad field of transportation, they are exceeded in the even larger field of stationary engineering represented by the huge light and power plants for municipal and manufacturing service, where the utilization of the exhaust steam in low-pressure turbines has made possible economies of from 30 to 100 per cent—this last result having been attained at the large station which furnishes power for the New York subway.

## DOES RADIUM EXIST IN THE PURE STATE?

THE French scientist G. Le Bon doubts whether metallic radium exists. In fact, we are only acquainted with the salts of the supposed metal, such as the chloride or bromide, and the probability of its existence is deduced only from the presence of some rays of the spectrum and an atomic weight which is somewhat theoretical, seeing that it has varied according to the observers. M. Le Bon has been of the opinion for eight years past that the existence of radium is doubtful. He considers that the properties of the supposed metal might be due to certain unknown combinations analogous to the equally unknown combinations which give phosphorescence to some of the sulphides. It is observed in fact that a pure sulphide is never phosphorescent, but when mixed with some traces of different bodies it becomes brilliantly phosphorescent. This point has been discussed in various papers presented to the Académie des Sciences. He had occasion to mention his views about radium to the late Prof. Moissan, and this well known chemist had in fact come to the same conclusion, having the idea of separating radium from its compounds. Death overtook him before he could carry out these researches. A tenth of a gramme of substance would be needed by a good chemist, but probably several operations would be required in addition. An expense of $10,000 would be incurred. M. Le Bon thinks that from chloride of radium we would extract simply barium and nothing more. The experiment, even through transforming a body worth $20,000 a gramme into a comparatively worthless metal, would be of great interest, for it would prove that radio-activity which gives out considerable force can be produced by certain combinations.

M. Georges Claude of Paris brings out the following points regarding the future uses of oxygen, seeing that this latter is now being produced on a commercial scale from liquid air. He shows that oxygen can increase by 40 per cent the yield of the reactions which serve as the base of the fixation of nitrogen by the electric arc, and it can improve the manufacture of ozone by nearly 300 per cent. Such results promise to be of great interest in many of the industries. The Belgian firm of Ougree Marihaye has recently ordered from the Paris Liquid Air Company three apparatus for producing oxygen, and these each have a yield of 200 cubic yards of pure oxygen per hour. Such apparatus will be used for experiments in blast furnace working, to observe the action of a considerable proportion of oxygen mixed with the air, which is sent into the blast furnaces. As to the price of oxygen, although this may be comparatively high when we consider only small quantities, the result changes when we come to using oxygen apparatus of the present kind, and we may count upon a price of 0.64 cent per cubic yard with apparatus of a large output such as we mention. However, even larger apparatus can be built in which no less than 1,000 cubic yards of gas per hour can be produced, working at a pressure of 10 atmospheres and furnishing 1.5 cubic yards per horse-power hour. In such case the price per cubic yard will fall as low as 0.5 cent. By using hydraulic power the cost of production can be still lowered. Oxygen plants of the present kind will be of great advantage in the way of small space occupied, seeing that a small factory occupying [illegible] [illegible]

## ENGINEERING.

**The German** estimate of aeronautical statistics for the year 1910 is that Germany will have fourteen dirigibles and five aeroplanes; France, seven dirigibles and twenty-nine aeroplanes; Italy, three dirigibles and seven aeroplanes, Russia, three dirigibles and six aeroplanes and England, two machines of each kind

**The activity** in railroad construction in the North west is answerable for the construction of several important bridges across the larger rivers A notable instance of this is the Columbia River bridge on the North Coast Railway in Washington the permanent sub-structure of which will consist of twelve piers carrying a superstructure made up of nine Howe truss spans, and a draw span across the main channel

**A leading** southern journal speaks words of wisdom when it says that the policy of navy yard construction of battleships should be adhered to, even if it costs a trifle more than building in private yards Keeping our leading navy yards busy with warship construction not only serves as a stimulus to private contractors, but it has the important effect of maintaining the navy yard forces intact, with a large body of skilled workmen ready at all times to undertake emergency work

**The loss** of the Atlantic transport liner "Minnehaha" upon the much-dreaded rocks at the western end of the Scilly Islands reminds us again that in spite of the additional safeguards which have been introduced of late years in trans-Atlantic navigation the perils of the sea are still insistent The great success of the submarine bell on our Atlantic coast suggests that this device might be used to very good effect at the more dangerous points at the approaches to the British Isles

**Nobody** seriously disputes the advantages of the "Pay-as-you-enter" car Not the least among these is the reduction which it has made at least on certain lines, in the number of accidents Statistics compiled by the Chicago City Railway show that the complete introduction of this style of car on all trunk lines has resulted in a decrease of accidents of about thirty-two per cent, as compared with the number occurring during equal periods of service with the old style of cars which it replaced

**The building** of railroads through mountainous country occasionally necessitates some daring bridge construction A recent instance of this is the Assopus viaduct which forms part of a new line extending by way of Demirli to the Turkish frontier The structure which is 600 feet long and spans a gorge 330 feet deep serves to connect two tunnels which open from either side of the gorge The superstructure which is very graceful in design consists of latticed trusses carried upon two hinged arches The bridge is on a grade of about two per cent and the line is laid on a curve of four degrees

**Recent tests** at Sandy Hook of the resisting power of reinforced concrete as a defense against high powered projectiles confirm the calculations of the penetrating power of the twelve-inch gun It is stated that a concrete wall twenty feet thick heavily reinforced with steel beams, was pierced by a twelve-inch projectile fired at high velocity We understand that a similar attack is to be made with the new fourteen inch gun The blow delivered was sufficient to penetrate twenty two inches of armor plate and the reinforced concrete withstood the attack so well that it will probably be used in the construction of the new coast defense fortifications in the Philippines

**The electric** operation of trains through the Saint Clair tunnel is showing the same economies as compared with steam operation, as have been obtained in similar installations elsewhere According to the Electric Railway Journal the cost of coal for one year under electric operation was only thirty nine per cent of that for the last year of steam operation The total service charges were but sixty per cent of those for steam, and the sum of service and fixed charges was 84.5 per cent; which represents the operating economy of the new over the old service The cost of maintenance and repairs for the electric system is fifty-five per cent of that of steam during the same period

**Considerable interest** has been aroused by the launch of the new torpedo-boat destroyer "Paulding" at the Bath Iron Works She will be the first destroyer in our navy designed for the exclusive use of oil fuel Except for this, she is practically a sister vessel to the "Flusser" and the "Reid," and like them she will be driven by turbines, and must make a speed of 29½ knots on a four hours' run at sea. It is well here to correct the statement which recently went the round of the press, that the "Flusser" made 36 knots recently in the Gulf of Mexico. As a matter of fact, her speed on that occasion was between 30 and 31 knots. Her best speed was made on her acceptance trials, when she steamed at an average speed of 33.75 knots. The fastest destroyers are the oil burners of the British navy, which made on trial between 35 and 36 knots.

## ELECTRICITY.

**In Rochester, N. Y.,** a good system of electric light and telephone wiring is in use, whereby unsightly pole lines on the streets are done away with The system is applicable chiefly to the residential districts. The lines are placed in underground conduits in the streets but instead of making connections with the houses directly from the underground conduits, a pole line is erected in the back yards of each block and this pole line is connected to the conduits by an underground branch at each side street This obviates the necessity of having a manhole in front of each house

**An application** was recently made for a permit to lay conduits along the new Baltimore and Wilmington road These are to form part of an underground trunk system connecting Boston New York Philadelphia, Baltimore and Washington, in which the American Telephone and Telegraph Company will run its lines The conduits will be laid just below frost line and will contain a hundred wires which can be tapped at any point It is stated that the system will serve as an auxiliary for the overhead wires which occasionally are put out of order by severe storms It is expected that after the line connecting Boston and Washington is completed, the system will be extended West and South

**Storage battery** locomotives are being used in certain mines of Germany These locomotives are considered less dangerous than the ordinary electric locomotive for the reason that no wiring is necessary in the mines and they can be incased completely to prevent ignition of gases by means of a chance spark The locomotives are each provided with two sets of batteries one of which is being charged while the other is operating the locomotive The batteries are seldom more than two thirds discharged so that the recharging takes but a short time In one type of locomotive of twenty horse-power the batteries contain ninety cells each with a capacity of 71 ampere hours The storage battery locomotives range from 8 to 32 horse power

**Whenever a** cable message is sent to an inland city, it is necessary to transcribe the message from the cable receiver and re-transmit it by hand over the land lines to its point of destination Heretofore it has been impossible to send a message directly to the inland city by means of relay connection with the overland wires for the reason that the cable signals are of too fluctuating a character and too sensitive to operate an ordinary telegraph relay Recently a system has been devised which promises to make direct connection between the cable and telegraph systems commercially practicable A very sensitive relay is used and the character of the signal is changed so as to obviate the usual fluctuations By means of this new system a cable message was recently sent from Canso Nova Scotia to New York a distance of 800 miles and here relayed to Chicago

**The installation** of a complete telephone system for the stage of the New Theater in this city illustrates not only the variety of uses to which the telephone is put but also the vastness and complexity of the up-to-date stage The stage telephone system has nine stations on the stage and twenty five floor stations with two switchboards or central stations Through these centrals inter-communication with the other stations may be had From one of these central stations the technical director controls the operations of the stage hands, while the other board is the stage manager's station The regular stations are placed in the prompter's booth the electrician's booth the stage galleries and one is located near the orchestra leader Calls are made by operating push buttons from either of the central stations and they serve to flash a bull's-eye signal or to operate a buzzer, depending upon which of two buttons is pressed The theater is also equipped with a telephone system used for carriage calls

**The Pennsylvania's tunnel** and terminal signal installation is the largest single installation of its kind ever made in this country While most people realize that signals play an important part in protecting train movements especially where traffic is congested, the investment made in these devices is far beyond the general understanding Development in signaling in recent years has been tremendous and has proceeded chiefly along electrical lines Complete signaling and interlocking of a double or four track road requires a large amount of electrical apparatus and the introduction of electrical propulsion complicates the situation We are informed by the Kerite Insulated Wire and Cable Company, who supplied the wire and cable for the Pennsylvania Terminal that frequently the cost of electrical wires and cables is from 20 to 30 per cent of the entire cost of the installation Not only from the standpoint of safety, but from that of reliability and punctuality of train service it is necessary that the wires and cables controlling the intricate apparatus should be the best Millions of feet of wire and cable conductors are being used in this installation

## SCIENCE.

**Prof. W. W. Campbell,** director of the Lick Observatory, has telegraphed to Harvard College Observatory that the bright sodium D line has been photographed in the spectrum of Halley's comet by Wright.

**Prof. Charles Chandler** was honored in New York city recently on his retirement in his 74th year from active service A banquet was tendered him at the Waldorf Astoria hotel The banquet was attended by many of New York's most distinguished scientists

**Commander Peary's** arrival in England was attended with much ceremony A regiment of reporters met him at Plymouth Members of the Royal Geographical Society as well as the London Naval Attache welcomed him to London With Commander Peary is Capt Bartlett, who accompanied him to the pole A special gold medal was presented to Commander Peary by the Royal Geographical Society and a replica in silver to Capt Bartlett

**A letter** dated May 1st 1910 has been received at Harvard Observatory from Prof D W Morehouse of Drake University stating that "This morning at 4 o'clock Halley's comet had a short bright tail projecting toward the sun Two bright rays bordered the outer part of this sector forming an angle with the nucleus of about 86 degrees The south preceding one was much the brighter The nucleus was surrounded on the sun side with distinct nebulous sheaths Smyth's observation of October 11th 1835 was vividly recalled A photograph of 11 minutes exposure showed a tail of over 2 degrees in length"

**The lowest** atmospheric temperature ever observed, −68 deg C (−90.4 deg F) was recorded on January 15th 1885 at Werchojansk in Eastern Siberia a little north of the Arctic Circle No lower temperature than this has been experienced by any Arctic or Antarctic expedition A temperature of −59 deg C (−74.2 deg F) was observed in 1876 at 82½ degrees north latitude and the lowest temperature observed by Nansen, at 85 degrees north latitude was −53 deg C (−63.4 deg F) The assertion of Dr Cook who claims to have observed a temperature of −64 deg C (−83.2 deg F) at 74 degrees north latitude in February 1908 cannot be accepted without reserve

**The United States Weather Bureau** has issued instructions to all its regular stations calling for observations on the 17th 18th and 19th of May of any optical, electrical or other phenomena that may be occasioned by the passage of the earth through the tail of Halley's comet Up to date the development of the tail has been disappointingly slow and it may not extend so far as the earth on the date of transit should it do so however it can hardly fail to make its presence manifest by disturbances in the atmosphere recognizable by the trained observer if not by the layman Such phenomena as mark the occurrence of an abnormal amount of dust in the atmosphere—e g red sunsets Bishop's ring and the singular noctilumlnous clouds that were frequently observed after the eruption of Krakatoa are especially to be looked for

**A monograph** bearing the title "Quality of Surface Waters in the United States" has been issued by the United States Geological Survey The volume which is the work of R B Dole contains the results of over 5,000 mineral analyses of water from the principal rivers of the United States east of the Rocky Mountains Daily samples of water from nearly 200 stations were collected for a year, united in lots of ten consecutive samples from the same stream and station and the composition subjected to analysis The analyses giving as they do the average composition from day to day and information regarding change of water level wherever available form the most complete collection of data regarding the quality of American rivers that has ever been published They are on this account particularly valuable to managers of industrial plants and water works

**During the** past winter Prof Hergesell of Strasburg president of the International Committee on Scientific Aeronautics carried out a series of daily meteorological observations with sounding balloons over the Atlantic Ocean in the region between Teneriffe and the West Indies The average altitude attained was 15,000 meters and the maximum 19,600 meters which is the record for such observations at sea The lowest temperature yet measured over the sea was also attained viz −80.5 deg C (−112.9 deg F) During December a strong trade wind average 14 meters per second, blew over the Atlantic up to an average altitude of 5,000 meters Immediately above this there was an unusually strong anti trade which had at an altitude of 8,000 meters a velocity of 30 to 40 meters per second The latter wind must have carried an enormous volume of warm air from the tropics to Europe and the unwonted strength of this current may have had something to do with the abnormally mild winter that has prevailed over that continent The isothermal layer was reached at an altitude of 16,000 meters, i e, 4,000 to 5,000 meters higher than it occurs, on an average, over Europe

# The Porhydrometer—An Apparatus for Weighing Ship Cargoes

BY THE ENGLISH CORRESPONDENT OF THE SCIENTIFIC AMERICAN

An ingenious apparatus has been perfected by an Italian engineer, Signor Emilio de Lorenzi, the function of which is to indicate automatically the weight of a ship's cargo. This device, which is called the "Porhydrometer," is of simple construction and operation, and works with remarkable accuracy—the results being within 0.001 per cent. Moreover, it is easy of installation so that vessels already in service can be equipped therewith as readily as those in course of construction.

The operation of the instrument is based upon the principle that a body floating in a liquid no matter what its density may be displaces a quantity of that liquid exactly equal to its own weight. The apparatus comprises merely a float or "aerometer" placed in a chamber filled with water, which is in communication with the outside of the ship. Consequently, as the vessel sinks deeper into the water while being loaded or *vice versa* when the freight is being discharged, the level of the water in the float chamber must rise or fall in coincidence with the level of the surrounding liquid outside. The float itself being fixed it becomes more or less deeply immersed in the water in the chamber with a consequent alteration in its apparent weight.

The aerometer is connected and balanced by levers so that by the adjustment of the balancing weights the volume of water displaced by the aerometer at any particular draught is accurately gaged. The alteration in apparent weight being read on the weighing machine or recording instrument and therefrom the weight of any cargo taken on board or discharged is easily determined.

The principle of the apparatus may be more comprehensively realized by reference to the explanatory illustration which shows the midship section of a vessel with the porhydrometer in position. The float chamber *A* is placed vertically over the longitudinal and transverse center of the ship and extends from a point 1½ to 2 feet below the line of flotation when the vessel is empty to a convenient height above the load line. This chamber is connected to the surrounding liquid by means of a smaller pipe *B* to a valve on the skin of the vessel, or to some other convenient sea water connection, a special tube being unnecessary so long as an uninterrupted flow of water to the float chamber can be secured so that the water level within may be exactly as that outside the ship. In the large float chamber *A* is immersed the aerometer *C* being suspended from, and balanced by a horizontal lever *D* having its fulcrum at *E* the other end being connected to a steelyard weighing machine at *F*. The aerometer is generally made heavier than its displacement, but this is immaterial since it is in a condition of equilibrium. The float extends downward sufficiently to bring its lower end below the plane of flotation for light loading, and sufficiently far upward to bring its upper end above the plane for the maximum draught. Moreover, its profile is such that the area of the float at any point of cross section bears a constant ratio to the area of the ship at the same level.

As the vessel becomes immersed through the superimposition of any weight such as cargo, the draught increases and accordingly the water in the float chamber rises to a higher level, the aerometer itself consequently being immersed deeper into the water, and by increasing its displacement reduces its apparent weight as already mentioned. This difference of weight creates a downward pull on the opposing arm of the lever, where a counterweight remains unaltered. As the steelyard is connected to the main lever *D* by tie rods or links the exact amount of tension is registered that is attributable to the disturbance of the balance on the main lever through the increased displacement.

The vital part of the invention lies in the aerometer. Alteration of trim or inclination of the vessel cannot by any means upset the accuracy of the instrument. It is in short an absolute gage of the vessel's displacement. Should the cargo be placed right aft or forward it will be weighed exactly the same as if placed near the center of the vessel, since the draught directly under the instrument is the mean of that fore and aft. The whole of the parts of the apparatus are standardized with the exception of the aerometer, which must be properly designed and carefully adjusted, its form being made to correspond with that of the ship.

Numerous tests with the apparatus have been carried out in England, and the accuracy of the weight readings, irrespective of the size of the vessel, have been remarkably conclusive. It can be applied to

Recording instrument of the porhydrometer.

any type of craft with equal facility and infallibility—to a small lighter as easily as to a transatlantic liner. At the present moment arrangements are being made for its installation upon a 10,000-ton vessel. In this case the diameter of the float will be about 9 inches. For a small lighter it averages about 3¼ inches diameter at the top by about 2⅞ inches at the lower extremity. So sensitive is the apparatus that it will indicate the weight of a person stepping on board.

Thus it will be seen that the captain of a vessel always possesses a means of determining exactly the weight he has on board. For those vessels engaged in long journeys, necessitating bunkering at intermediate ports, it is of far reaching importance, since it enables the captain to ascertain precisely how much fuel he has shipped. This is a valuable point, inasmuch as at many foreign ports short weighting is by no means an uncommon practice, and vessels are often mulcted for a considerable sum per annum in payments for misrepresented quantities of coal.

The function of the invention is also carried to a further and important feature. It will inform the captain the exact weight of water he has in his ballast tanks. Also, should the vessel spring a leak the fact is instantly communicated to the captain by the apparatus registering an increased weight or displacement due to filling with water. In cases of collision and grounding the incursion of water is similarly conveyed, the apparatus being equipped with an electric alarm bell, which conveys intimation of the danger to the captain. No discrepancies in the readings can be introduced by variations in the density of the water in which the vessel may be floating, for such cannot affect the fundamental principle upon which the apparatus works.

It will be seen that by the introduction of the apparatus the ship itself is practically converted into a huge weigh bridge. The Italian government submitted the invention to searching tests and was so convinced of the accuracy of the records that its customs authorities have been ordered to accept porhydrometer readings as correct. To the shipowner this is no slight concession, since in regard to Italy, instead of paying 4.5 cents per ton in weighing dues, vessels fitted with the porhydrometer only pay 1.25 cents per ton.

THE PORHYDROMETER—AN APPARATUS FOR WEIGHING SHIP CARGOES.

### Influence of Phase and Rotation upon the Brightness of Illuminated Spheres.

The total luminosity of the moon varies according to the proportion of its illuminated hemisphere which is turned toward the earth, that is to say, in accordance with the "phase" of the satellite. Mercury and Venus show similar, but smaller differences of phase and brightness. The exterior planets vary in phase so little that the variation in their brightness is barely perceptible. The brightness of planets can be measured by the astrophotometer, and the dependence of the brightness upon the phase can be expressed by a curve. As it seemed possible that some information in regard to the surface of the planets could be obtained from the study of such curves, Von Aufsess has made a series of experiments to determine the relation between brightness and phase in the case of illuminated masses of limestone, sandstone, granite, and other materials of spherical and other forms. The measurements of brightness were made in a completely dark room. The artificial plant was illuminated by a Nernst lamp, not directly, but by reflection from a plane sheet of glass, through which the object could be observed in the "full" phase. The lamp and the reflector were mounted on an arm which could be turned around the object in order to vary the phase.

When the results were plotted, the curves representing the brightness as a function of the phase were found to fall into two classes, according to the character of the material to which the globes were composed. Globes of light colored material gave curves concave below, while the curves produced by globes of darker material are concave above. Small elevations and depressions, glossy surfaces, etc., were found to produce comparatively little effect upon the curves, the character of which was, in general, decided almost entirely by the lightness or darkness of the surface. The curves produced by Venus and the moon are concave above. Hence it appears probable that the surfaces of these two planets are formed of dark colored material.—Prometheus.

In a recent issue of Nature the difficulty experienced in hot countries in keeping small accumulators in working order is referred to, and it is pointed out that this is probably due to the cells being filled with dilute acid of density 1.190 at a temperature of 30 deg. or 35 deg. Cent. While this is a proper density to use in a climate where the temperature is 15 deg. to 30 deg. Cent., corresponding to a 20 per cent mixture, it is too high for a hot climate, where it really represents a 28 per cent mixture; a density of 1.170 or even 1.150 is more suitable.

## THE NEW EIFFEL PHOTOGRAPHIC HELIOGRAPH.

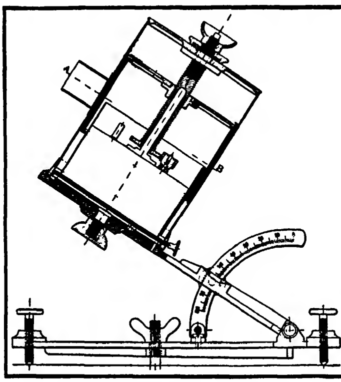
BY JACQUES BOYER.

Bouguer, in order to measure the luminosity of the sun's disk, allowed a beam of sunlight to enter a dark room through a small aperture, behind which a converging lens was placed. The diverging cone of rays, beyond the focus of the lens, was intercepted by a screen, forming a circle, the brightness of which was not too great to be measured by the ordinary methods. The brightness of the sun was assumed to bear the same ratio to that of the circle on the screen that the area of the circle bore to that of the aperture through which the light entered. At a later date (1844) Fizeau and Foucault employed the photographic process which had just been discovered by Daguerre to compare the brightness of the sun with that of artificial sources of light. The quantity of light received by a unit of area of the solar image formed at the focus of a telescope is proportional to the clear aperture of the object glass. Fizeau and Foucault received the image of the sun on an iodized plate of silver. In successive experiments they varied the aperture of the objective and regulated the duration of the exposure so that the final tint assumed by the plate and, therefore, the quantity of silver iodide decomposed, was the same in each case. In this way they proved that the required length of exposure, within certain limits, varied inversely in proportion to the aperture of the objective. In other words, the total chemical effect was found to be (within the range of exposure) proportional to the total quantity of light received by the image during the exposure. Then, by comparing the image of the sun with that of a circular area, of the same apparent diameter, of the positive carbon of an electric lamp, they proved that the chemical effect is proportional to the brightness of the source of light. This relation, however, did not appear to extend indefinitely, for the quantity of silver reduced, which was at first proportional to the length of the exposure, tended toward a fixed limit when the exposure was greatly prolonged.

In 1881 the great advance which had been made in photography enabled Janssen to employ very sensitive plates, in which the total chemical effect remained proportional to the duration of exposure within very wide limits. Jordan devised a heliograph in the form of a perforated cylindrical box containing a sheet of ferro-prussiate paper, and Richard constructed another instrument based on the photographic action of the solar rays.

Campbell, on the other hand, made use of the heating effect of the solar rays for the purpose of measuring the effective annual duration of sunlight, i. e., the aggregate time during which the sun is not veiled by clouds, a quantity which plays an important part in the processes of vegetation. Campbell's heliograph consists of a sphere of glass, mounted on a horizontal base, in a place exposed on every side, so that the sun is visible from its rising until its setting. A groove in the spherical mounting allows the introduction of a strip of cardboard, which forms a circular arc at such a distance from the spherical glass lens that the image of the sun, formed by the lens, is always on the strip. The cardboard is carbonized by the concentrated solar rays at the spot where the image is formed and, owing to apparent diurnal motion of the sun, a black line is traced on the card. If the sun shines all day without intermission this line is continuous, but if the solar rays are intercepted by fleeting clouds the trace consists of a number of separate portions, the positions and lengths of which show when and how long the sun has shone. The apparatus is easily set up. It is necessary only to level the base, to place the noon line, marked XII on the card, opposite a fixed mark on the frame, and to set the instrument so that the sun's image falls exactly on this line at the instant of true noon. In the improved form of the instrument designed by Stokes the frame has three grooves, at different heights, in which three sorts of cards are placed. The shortest cards are placed in the highest groove and are used between November 5th and February 5th, the longest cards are placed in the lowest groove and are used between May 5th and August 5th, while the cards of intermediate length are placed in the middle groove and are used during the remainder of the year.

THE EIFFEL PHOTOGRAPHIC HELIOGRAPH.



VERTICAL SECTION OF THE EIFFEL HELIOGRAPH.

Eiffel has recently invented a photographic recording heliograph which has been used for some time at the central meteorological bureau of France and at the Juvisy observatory. It consists of a cylinder which is mounted on a shaft parallel to the earth's axis, and is turned by clockwork at the rate of one revolution in twenty-four hours. The sun's rays enter the cylinder through an aperture in its convex surface which is surrounded by a hood for the exclusion of diffused light. An inner cylinder, covered with photographic paper, is supported by a nut which can move along the shaft of the outer cylinder which shaft bears a screw thread. A guide, attached to the case of the clock work, prevents the inner cylinder from rotating. Hence as the outer cylinder turns, the inner cylinder is compelled, by the screw, nut and guide to move along the shaft without rotating. The photographic paper is surrounded by a screen, which has various degrees of transparency in its various parts corresponding to the average intensity of sunlight at different hours and seasons. As the outer cylinder rotates, its aperture is always directed approximately toward the sun and in consequence of the motions of the two cylinders, the entering pencil of light traces a helicordal line on the paper which is wide enough to serve for a number of days. No new conclusions can be drawn from the photographic records made by the Eiffel heliograph until after the instrument has been in continuous operation for several years.

## CARDIN PROCESS OF PHOTO-SCULPTURE.

The idea of employing photography as an aid to sculpture soon followed the invention of the daguerreotype. Fifty years ago Willème devised a process in which the sculptor's model was photographed simultaneously by twenty-four

Fig. 2.—Cardin's apparatus for [illegible] the [illegible] from the front, back, and both sides simultaneously with a single camera.

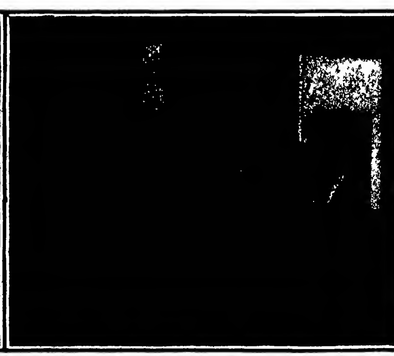


Fig. 1.—Cardin's apparatus for modeling from four photographs.

THE CARDIN PROCESS OF PHOTO-SCULPTURE.

cameras, arranged in a semicircle. A paper positive is made from each of the negatives and the twenty-four prints are cut out along the outline of the figure, and are then cut in two vertically. The forty-eight profiles thus obtained are assembled radially about a vertical axis in their proper relative positions. By filling in the intervals with a plastic mass a fairly complete sketch of the figure is obtained.

This process may be varied as follows. A mass of clay or modeling wax is placed on a revolving circular platform, the circumference of which is divided into twenty-four equal parts. The approximate form of the model having been given to the mass by the usual methods, the outline of the figure in one of the (entire) photographs is followed with the tracing point of a pantograph, which is so constructed and arranged that its copying point plows a furrow in the mass of clay. The platform is then turned through one division and a second furrow is made from the second photograph. This process is repeated with each of the twenty-four photographs, and the clay between the furrows is carefully removed. A very skillful hand is required to perform this operation so as to reproduce every detail of the model, but the object of this and all other processes of photo-sculpture is to produce, not a finished statue or bust, but a sketch as nearly accurate as possible.

The new Cardin process possesses the advantage of requiring only one photographic camera. Fig. 2 illustrates the method of making the photographs required for a portrait bust. The sitter is posed, facing the camera, before a triple mirror, by means of which the back and sides of the head are photographed by reflection. As the sitter's face and the three virtual images formed by the mirrors are unequally distant from the lens, the four images formed by the latter are not in sharp focus in the same plane. For this reason the ground glass focusing screen is made in four sections, and the plate holder is contrived to hold four plates, side by side, but in slightly different planes. The same cause produces differences in the scales of the four photographs, but in making the enlarged copies which are employed in the operation of modeling, these differences are easily removed with the aid of the plummets which are suspended above and at each side of the sitter's head, and which appear in each photograph and indicate its scale.

The modeling apparatus is shown in Fig. 1. A vertical post rises from the center of the square iron platform $S$. Two photographs, a front view $T$ and a profile $E$ are supported in a vertical position by frames which slide in guides bordering two adjacent sides of the table. These sides are furnished with jointed supports which carry long rods, $A$ and $B$. The rods can slide lengthwise in their supports and can be inclined and moved vertically and horizontally by means of the joints of the supports. The rods are used horizontally if the bust is to have the same scale as the photographs, and are inclined for enlargements and reductions. The movement of the photograph frames in the guides is limited by fixed stops, so that the frames can be removed and replaced exactly in their former positions.

The rods and their supports are adjusted to bring the inner end of the rod $A$ into contact with a conspicuous point, the tip of the nose, for example, in the full face photograph $T$ and the inner end of $B$ into contact with the corresponding point of the profile $E$. The frames containing the photographs are then removed and the rods $A$ and $B$ are pushed inward in their supports until their inner ends meet. The point of meeting determines the position of the top of the nose of the bust. The post at the center of the table is covered with clay or other plastic material, which is built out until this point is established in tangible form. The rods are then drawn back, the photographs replaced and a second point of the face is established by a repetition of the process. In this way numerous points distributed over every part of the bust are fixed, each pair of adjacent sides of the table, and the corresponding pair of photographs, being employed, as required. The result is an almost complete sketch, obtained from a sitting of a few seconds. All of these operations can be performed by a skilled workman. The hand of the sculptor is called into requisition only to give a few finishing touches in another brief sitting, and to impress an individual artistic character upon the work.

## HALLEY'S COMET IN THE EVENING SKY.

BY HENRY NORRIS RUSSELL, PH.D.

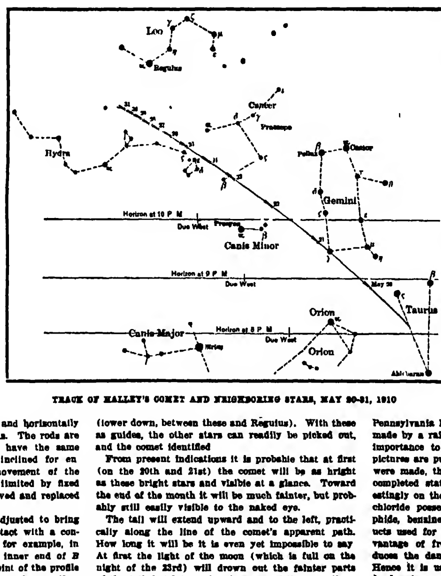
The average man will find by far his best opportunity to see the comet, which has occupied so prominent a place in public attention, during the last ten days of May. The accompanying map shows at a glance just what are the circumstances of its appearance. At first its apparent motion among the stars is very rapid, but later, as it recedes from us, it seems to stand almost still in the sky. Its distance from the earth is in round numbers 14 million miles on the 20th, 17 million on the 22nd, 28 million on the 26th, and 45 million on the 31st, so that it will appear to shrink and grow visibly fainter from night to night.

In addition to the stars near the comet's path, and the place of the comet for each night (at 10 P. M. Eastern Standard Time, or 9 P. M. Central Standard Time, etc.), the map shows the position of the horizon among the stars at certain hours, so that it is easy to estimate how high up they will appear at any time.

The given position of the horizon is exact for observers in latitude 40 deg. north (Pennsylvania, Ohio, Illinois, Utah, northern California).

Those south of this line will see the stars on the right (on the map or in the sky) somewhat lower, and those on the left somewhat higher, at the same hour. In any case it will be easy to identify them by their relative positions.

Those unfamiliar with the constellations may well begin with the four brightest stars: Regulus (at the end of the sickle-shaped group shown on the map), Castor and Pollux (close together), and Procyon



TRACK OF HALLEY'S COMET AND NEIGHBORING STARS, MAY 20-31, 1910

(lower down, between these and Regulus). With these as guides, the other stars can readily be picked out, and the comet identified.

From present indications it is probable that at first (on the 20th and 21st) the comet will be as bright as these bright stars and visible at a glance. Toward the end of the month it will be much fainter, but probably still easily visible to the naked eye.

The tail will extend upward and to the left, practically along the line of the comet's apparent path. How long it will be it is even yet impossible to say. At first the light of the moon (which is full on the night of the 23rd) will drown out the fainter parts of the tail, but later, when it is out of the way, these may perhaps be seen, though the comet will be so much farther off that, on the whole, it will hardly be so fine a sight.

In observing it telescopically, the eyepiece of lowest power, giving the largest field of view, will be most satisfactory.

Princeton University Observatory.

### The Elasticity of the Earth.

Some interesting experiments have recently been carried out by Prof. Milne, F.R.S., the well-known authority on seismology, to demonstrate the elasticity of the earth especially under the influence of the tides. Some years ago he showed that valleys during the day are of greater width than at night, there being an expansion or opening out under the action of the sun and a contraction or closing up in the hours of darkness. He also showed by means of seismographic records secured at his observatory at Shide, that the Isle of Wight alternately moves forward and backward with the variation of the tides, the greater pressure of the water at high tide in the English Channel as compared with that in the Solent and Spithead causing the island to be tilted upward bodily from the channel side.

His latest experiments in this direction have been carried out in connection with the Irish Sea at the mouth of the Mersey. A special type of seismic recorder has been devised and has been set up in an underground position at Bidston Observatory near Liverpool, some two miles from the water's edge. The apparatus comprises, as it were, a mast and a boom, such as is used in the professor's earthquake recorders, the boom being free, so that as the mast moves in one direction or another the boom can also move. A photographic recorder is connected to the apparatus so as to secure a permanent visual record of the oscillations. The instrument is far more sensitive than that employed for ordinary seismic operations, thereby indicating those very slight movements of the earth which the ordinary apparatus would ignore.

The records secured by this instrument conclusively prove that twice every twenty-four hours the opposite sides of the tidal basin are drawn closer together, the phenomena occurring at high tide when the increased volume and weight of water piled up in the Irish Sea and pressing on its bed causes the latter to sag somewhat. The action can be watched, for when the tide is flowing quickly and the tide is high the pendulum moves a considerable distance and keeps pace with the deflection due to the increasing load. At Bidston the weight of the tide off the mouth of the Mersey causes a deflection of about one inch in a distance of sixteen miles. As the tide ebbs and the weight is reduced the sag diminishes like a dent in an India rubber ball, and the banks on either side slowly recede from one another. The extent of this attracting and repelling movement would be more accentuated upon the instrument were the latter placed nearer the sea, and Prof. Milne points out that for this reason observatories should not be situated too near tidewater. The regular alternate movements of the apparatus in opposite directions every six hours not only, as it were, record the extent of the elasticity of the earth's crust, demonstrating that it is responsive to pulls and strain to a far greater degree than is generally believed, but also weigh the tide itself. The result of these experiments should provide a new field for investigating tidal forces and phenomena, and possibly contribute to our knowledge thereof.

### The Current Supplement.

Almost the entire issue of the current SUPPLEMENT, No. 1793, is devoted to a complete description of what is known as the New York Tunnel Extension of the Pennsylvania Railroad, the costliest improvement ever made by a railroad, and one of the most far-reaching importance to industry and to the traveler. Many pictures are published, showing the excavations which were made, the progress of the work, as well as the completed station. Dr. Otto Hoffmann writes interestingly on the system of the universe. Carbon tetrachloride possesses in comparison with carbon disulphide, benzine, gasoline, and other petroleum products used for the extraction of oils and fats, the advantage of freedom from inflammability, which reduces the danger of fire and the cost of insurance. Hence it is used frequently as a harmless substitute for benzine and gasoline in cleaning clothes. An article on the subject appears in the SUPPLEMENT. Mr. Henry A. Wise Wood's excellent paper on Modern Stereotypy is concluded.

Recently Mr. W. Casmey, of Leeds, read a paper before the Rotherham Engineering Society on "Engineering in the Boiler House." Mr. Casmey stated that there was an indication that the factory chimney would be supplanted by mechanical drafts or fans, as the cost of maintaining steam by such methods was only about one-sixth that of chimney draft. He pointed out that while steam gages and water indicators had long been in use, stokers had no assistance in ascertaining the volume of air necessary for combustion. A full combination indicator had, however, been invented for this purpose, consisting of a gage actuated by the draft of the chimney and having a graduated scale giving the pounds weight of coal burned to the square foot of grate per hour.

# Wireless Telegraph Apparatus for Contestants of the Glidden Tour

BY RENÉ HOMER

In the district selected for the annual Glidden tour this year, ordinary telegraph communication will be very difficult, and at times impossible. In 1909, although the tour passed through a comparatively well-settled country, the whereabouts of several of the contestants were often unknown for hours. One car, for instance, failed to report at the night control, and no one knew what had happened until the next morning. On another occasion a passenger was injured in an

Bamboo aerial set up in car.

accident, and nothing was known of the matter until it was reported by a belated tourist at the night checking in. Many minor difficulties were responsible for considerable delay that could have been prevented if the cars had been in communication with the last control.

The Chalmers-Detroit Company propose to keep in touch with the contestants by means of wireless telegraphy. Complete plans have not been worked out yet, but it seems probable that some such scheme as the use of three field wireless stations will be favored, two of the stations carrying on communication, one of them being in touch with the wire system, while the third station is being established at some advantageous point ahead of the contestants. The exact details of the plan will be furnished after a trial car has had a chance to go over the worst portions of the proposed route.

In the early part of March successful wireless telegraph tests were made for the Chalmers-Detroit Company between one of its cars in Central Park, New York, and the old Terminal Building at Park Avenue and 42nd Street. The distance varied from one and one-half to three miles in the trial from a moving car, while the experiments with the portable field stations showed that this type of apparatus at least would be able to carry on certain communication up to fifty miles, as the field station was able to keep in communication without any trouble with the Metropolitan and Manhattan Life towers and another wireless station at Newark, N. J. Later, communication was maintained between a car on the New Jersey highways near Trenton to the "sparkless" wireless station on the Land Title Building at Philadelphia, nearly thirty miles away.

The receiving station for running automobiles comprised a 7-foot aerial in connection, through a loose coupling, with a variable and a fixed condenser, a detector of the audion type, telephone receivers, and a high and low voltage battery. The sending set comprised two storage cells, a 10-inch spark coil, two Leyden jars, and a 3½-inch "radiotone discharger" similar to those used at the Metropolitan and Manhattan Life stations. This apparatus, which worked successfully up to three miles, the farthest distance tried, would probably operate for several miles farther. The ground was secured by drawing between the rear wheels a bicycle tubing frame supported on four small wheels mounted on roller bearings, the middle space being occupied by three 8-inch steel wheels with slide bearings arranged so as to allow the weight of the wheels to keep them in contact at all times with the road. On the macadamized roads of the park this system of grounding worked fairly well, although on the sandy roads of New Jersey, where the subsequent tests were made, a great deal of difficulty was experienced in properly maintaining the ground. The spraying of water over the contact wheels by means of a small rubber tube leading up into the car partially overcame this trouble, and no doubt subsequent experiments will provide a suitable way of securing a satisfactory ground contact, although it is true that probably for some time to come the speed of moving cars must be considerably limited for successful wireless work. The cars in the tests ran only about ten miles an hour.

Field stations which can be put up in five minutes can be operated more successfully, and the same apparatus used in the automobile by stopping the machine and securing proper ground has a range of about ten miles. The sending circuit of the field stations used in the longer distance tests was the same as that of the moving stations, with the exception that three storage cells instead of two were used, and another 10-inch spark coil was connected in parallel with the first coil, so as to be operated from the same key. This gave a range of about fifty miles.

The field sending station was provided with a 100-foot aerial secured at one end to a spreader attached to a 48-foot bamboo telescope mast and leading down diagonally to the top of a 12-foot mast about 90 feet away and thence back to the wireless apparatus about midway between the two poles.

Two of the photographs show the first successful test, in which a 35-foot aerial and a 6-inch spark coil actuated by one storage cell were used. With this apparatus, from Central Park, communication could be held with the laboratory at 42nd Street, about one and one-half to two miles away.

In the more recent tests additional condensers, storage cells, and audion receiving accessories were used. The closer view shows a radion detector in use (top of the box to left) while a perikon detector is shown unconnected on the table in front of the other apparatus. The box upon which the operator is sitting contains the interrupter, spark coil, and discharger, which are inclosed on account of their delicate nature and because they have not yet been protected by patent. In the newer station all this apparatus is carried in the automobile, and there is no necessity for setting up the apparatus on the ground, although the soap box does indeed make an admirable table for a wireless station.

In the coming tour it is proposed to send two scout

Automobile wireless equipment.

cars ahead of the regular contestants, each one of which will carry the complete field set of even greater range than that which every car can carry. Points where the telegraphic facilities are poor or impossible will be picked out and the two cars will arrange to be at stations at these points just ahead of the pilot car, one station being equipped for business while the other is taking care of the telegraphic business of the tour. In this way one of the two field stations will be in operation all the time, while the other is being set up at the next point along the route.

---

Disastrous as the floods in France have proved for the railways, a worse disaster occurred one day last winter in America. Three days previously a warm wind arose in the State of Nevada so suddenly as to melt all the snow. The result was such a torrent as to entirely wash away 100 miles of the San Pedro, Los Angeles and Salt Lake line south of Caliente. The route of this line was known to be rather liable to this, but was chosen as it saved much distance. Soon after its construction it was undermined by a storm, which did over $500,000 damage to it. The engineers are now engaged in surveying the district in order to find a safer if longer and most costly route. Whichever route be chosen, it will be from six months to a year before the line can be built and the cost will, it is said, be from ten to fifteen million dollars.

The automobile equipment with its aerial and wireless apparatus.

Sending wireless messages from an automobile.

WIRELESS TELEGRAPH APPARATUS FOR CONTESTANTS OF THE GLIDDEN TOUR.

The practical success achieved with the gasoline-propelled motor sleighs on the Shackleton and Charcot polar expeditions has prompted Capt Scott to include a vehicle of this type for his forthcoming dash to the south pole This vehicle is, however, distinctly different from the motor sleighs hitherto used In the two previous cases the front of the car was mounted on runners or skates, a chain and sprocket with spuds which gripped the snow and ice being fitted at the position occupied by the wheels in the ordinary motor car In the new sleigh, however, what may be termed an adaptation of the pedrail or caterpillar system has been resorted to, which imparts a greater degree of efficiency to the vehicle, and enables it to surmount obstacles and to travel over rough ice and snow with ease In view of the conditions prevailing and the work it is intended to fulfill in the south polar regions, the engine is of a special type It comprises four vertical cylinders, cast in pairs, and developing twelve brake horse-power

The sleigh is fitted with a runner, upon which bear the rollers of the chain. The latter passing between this runner and the ground supports the whole vehicle and propels it as the wheels revolve There are no brakes provided, as the big reduction ratio of the worm renders it completely irreversible, so that brakes are not necessary Similarly, steering gear is dispensed with, as such is not requisite, for in any open area such as an ice field steering is not demanded When it is required to deviate to the right or left ropes attached to the front of the frame can perform this function Turning sharp corners, under these circumstances, is admittedly exceedingly difficult, but when working in its designed sphere this drawback will not be serious, as sharp turning can be generally avoided.

The sleigh has a substantial wooden frame, and underneath is fitted a large undershield extending from end to end so as to present a perfectly smooth surface to the snow When the sleigh is under way a curious fact is observable. The chain, where it

# THE FLIGHT FROM LONDON TO MANCHESTER

## THE AVIATORS' OWN ACCOUNTS

**Both White and Paulhan have furnished the London Daily Mail with accounts of their remarkable flights.**

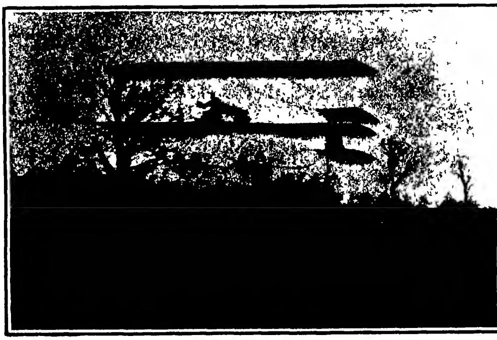
**White rose at 2.30 A. M Twenty-four minutes later he was in the air It was so dark that people were groping about with lanterns**

"As I stood by the side of my aeroplane," White states, "there was utter blackness facing me, faintly relieved in the distance by two or three twinkling lights, which I knew to be those of Roade station

"My start was a confused jumble of scattering lights, which swept away swiftly below me I could not judge my run along the ground, but I rose as speedily as possible. Directly I was in the air the lights of the railway station showed clearly below me, and I headed toward them I could see absolutely nothing of the ground below me, it was all a black smudge

"I went right over the railway station lights and then, fortunately only for a second or so, my engine missed fire and I began to sink toward the inky darkness below me. I could have picked no landing, and it would have been a swift, steep glide to I know not what And then, to my joy, my engine picked up again and I rose once more.

"Great difficulty presented itself in knowing in the darkness whether I was ascending or not. I had done no night flying before, but I soon became accustomed to watching closely the movements of my elevating plane, which was silhouetted before me against the sky



Grahame White leaving Rugby.

"I steered on for a spell with nothing at all to guide me After leaving the lights of Roade behind, the gleam from an occasional signal box far below helped me, however, and so I picked my way through the night to Blisworth

"Here I felt surer of my ground and bore away to the left for Weedon Faint lights shone here and there Some, no doubt, were cottage windows and others, I think, were the head lights of motor-cars. I passed over Weedon, my eyes becoming more accustomed to the darkness.

"On I flew The weirdness of the sensation can scarcely be described I was alone in the darkness, with the roar of my engine in my ears. As I glanced back small bright flashes of light, the discharge of the exhaust gases from the motor, flashed out in the night

"Then I lost my way, with no railway lights to guide me, for a spell. I steered off to the right. I wheeled and turned, wondering what I should do, but then a light to my left caught my eye, and I worked my way back to the railway line again

"At a little inn by the roadside near the village of Crick a friend had promised to draw up his motor car, shining its headlights upon the wall, to act as a guide for me I was keenly on the lookout for this unmistakable light sign, and, sure enough, I saw it quite distinctly below me soon after I left Welton station behind.

"I deviated a little from my course and headed for this patch of light. I saw the motor car moving as I approached, with its headlights throwing a great path of light down the roadway It set off at a breakneck pace, its driver evidently meaning to guide me on my way.

"Leaving the railway line on my left, I followed the light of the motor car, and for a mile or so I hovered almost directly above it, allowing it to act as my pilot. But while I was doing so I chanced to glance over to the left again. Coming down the railway line I espied a goods train. It was making for Rugby.

"This, I thought, will be a splendid guide, and so I swung away from the lights of the motor car and flew off till I was over the train I saw the lights of Rugby, flew over the town, and forged ahead

"Daylight began to come now, and from here on to the point of my descent in a field near Polesworth my struggle was not with the darkness, but with the wind

White's aeroplane after landing.

It was the fierce gusts which eventually brought me down."

Paulhan, too, seems to have been troubled by the winds, for he bears out White's account. He writes

"I had to fight the wind all the way from London. Not a moment's rest came to me in my battle against the gusts

"Glance at my altitude chart and you will see that I made rises and dips of as much as 120 feet always with the object of flying in the steadiest level of air I could find

"After the start I was going north for a long time before I sighted the special train which was accompanying me, but there was no mistaking it when it caught me up, with three loud toots of the whistle and a big white signal cloth flowing from the window of the rear coach

"It looked like a handkerchief from such a height but it told me all I could see that things were going well The wind whistled and so did I

"I flew until it was quite dark All I could make out beneath me was the smoke of the train once in a while and the occasional flicker of lights from a village

"I came down rapidly from 300 meters to 100, so that I could be more certain of my direction Then came the most exciting moment of my flight Darkness had fallen and before me I saw the lights of Lichfield I decided to alight in some convenient meadow before reaching the town and to do this I sank down to 150 feet. I was immediately above what looked like a large factory with a chimney I am now told it was a brewery And so, to alight safely in a field with no damage done, I made a fishhook turn, and my machine was now pointing toward London

"Suddenly my motor stopped Every drop of petrol had been exhausted and the machine swooped downward almost like a stone dropping

"What should I do? Beneath me was the brewery

Recharging the gasoline tank of White's machine.

THE FLIGHT FROM LONDON TO MANCHESTER.

and a certain smash, behind me was a narrow field, which was almost like a spider's web with its mesh of telegraph wires

"I had an imperceptible fraction of a second in which to make up my mind, and I decided to risk the telegraph wires As I sank I made a sharp twist right back on the line of my course, and was lucky enough to lift myself over the wires

"I went to bed at 1 o'clock deciding to start again as soon as it was light or even a little earlier I slept like a top for five hours

"It was still dark when I reached the narrow meadow beside the Trent Valley station in which my machine was lying My mechanics had worked well during the night The machine was charged with petrol and she was all ready for the start

Happily, favored with the headwind I was then facing though it was a following wind for my flight, I rose without difficulty, turned, and headed straight for Manchester

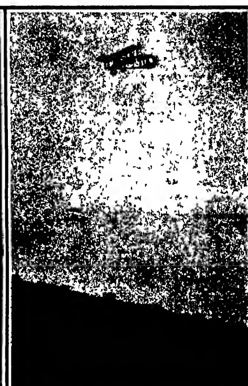
"Here was the end of my concern about the issue of the race Barring accidents, I was bound now to reach Manchester in safety and in good time, and there was no reason to anticipate accident, for I had surmounted the worst of the difficulties—that of a rise from a narrow field only 120 yards long above dim lanterns which were my only indications as to the whereabouts of the hedge.

"As soon as I got up I made a circle, followed the railway, and then set off for Crewe, fighting all the way against gusts of wind So certain did I feel of the road that I did not trouble to take my map on the second stage of the journey This was a mistake, for after leaving Crewe I thought the first station marked my landing place, but I could discover none of the marks I expected to find there, and I had to circle back toward London before I picked up the whitewashed marks on sleepers which directed me onward

"I made yet another mistake in my route, and had to curve in yet another circle backward, but at last I saw the new station at Burnage, which was my objective, and I saw the white marks in the field where I was to land

"I landed and I knew I had won All the way from London it had been a fight between me and a puzzling wind, and I had beaten the wind"

The crowd on Wormwood Scrubbs awaiting White's start.



Paulhan in full flight.

THE FLIGHT FROM LONDON TO MANCHESTER.

**Official Meteorological Summary, New York, N. Y., April, 1910.**

Atmospheric pressure Highest, 30 28, lowest, 29 57, mean, 29 93 Temperature Highest, 79, date, 30th, lowest 34, date 8th, mean of warmest day, 64, date, 5th, coolest day, 41, date, 8th; mean of maximum for the month, 63 1, mean of minimum, 45 8, absolute mean, 54 0, normal 48 1, daily excess compared with the mean of 40 years, 5 9 Warmest mean temperature of April, 54 in 1871 and 1910, coldest mean 41, in 1874 Absolute maximum and minimum of April for 40 years, 90 and 20 Average daily excess since January 1st 4 1 Precipitation 4 53, greatest in 24 hours, 2 23, dates, 25th and 26th, average for April for 40 years 3.30 Excess above normal 1 23 Accumulated excess since January 1st, 0 14 Greatest precipitation, 7 02 1874, least, 1 00, in 1881 Wind Prevailing direction, northwest, total movement, 9,169 miles; average hourly velocity, 12 7, maximum velocity, 44 miles per hour Weather. Clear days, 7, partly cloudy, 13; cloudy, 10, on which 0 01 or more of precipitation occurred, 11 Mean relative humidity, 63 1 Dense fog, 4th and 18th. Thunderstorms, 6th and 25th. Frosts Light, 14th, heavy, 13th

**COMPLETION OF THE PENNSYLVANIA RAILROAD TUNNELS AND TERMINAL STATION.**

As late as the year 1901 the Pennsylvania Railroad was employing ferries to land its passengers in New York city just as it did in 1871, when it first leased the United Railroads of New Jersey Ten years ago the system was hauling freight to Eastern cities over practically the same heavy grades as were to be encountered in 1875 To-day the company is completing a monumental improvement in and around New York city which will enable passengers to travel from eastern, western and Long Island points direct into Manhattan Island, arriving at a railroad station which, for convenience and for the beauty and dignity of its architectural appearance, probably outranks any similar building in existence.

During the past ten years the company has spent an enormous sum of money in straightening out its line to the East, and in cutting down grades, and in a few months' time freight trains which are already traveling over the new lines, on which they encounter no grades greater than twelve feet to the mile, will be run direct to large terminal wharves on the New Jersey shore of upper New York Bay, and ferried across to Bay Ridge, Long Island. The company is about to construct a four-track arch bridge across the East River near Hell Gate, and when this is completed trains will be run through Long Island from Bay Ridge to Port Morris, where connections will be made with the New York, New Haven and Hartford Railroad Passengers from the South, Southwest, and West, over the Pennsylvania Railroad system, by using the North River and East River tunnels and the Hell Gate bridge, will be enabled to travel without change of cars between New England and the West by way of New York city These stupendous works, which will have cost in the aggregate, including the revision of the western line, over $150,000,000, were conceived mainly during the administration of the late A. J Cassatt, former president of the company

Commencing at the western end of the New York tunnel system, we find at Harrison, New Jersey, a large terminal and transfer station, where passenger trains from the South and West drop their steam locomotives, and the electric locomotives, which haul them into New York city, are coupled on. The tracks run on a high embankment across the Hackensack meadows to Bergen Hill, where they enter the western portal of the twin tunnels. They descend on a grade of 1.3 per cent to a level about 100 feet below mean high water of the Hudson River, which level is reached about one-third of the distance from the Jersey shore The line then rises on grades of 0 5 and 1 93 per cent until the station yard is reached at Tenth Avenue The yard and the station, which have been excavated to an average depth of fifty feet below the original street surface, extend from Tenth Avenue to Seventh Avenue. From Tenth to Ninth Avenues the yard occupies more than the area of a city block, and from Ninth Avenue to Seventh Avenue the huge excavation covers the whole width between Thirty-first and Thirty-third Streets. The excavation covers therefore over five of the largest city blocks, and it involved the removal of over 3,000,000 cubic yards of material. Proceeding easterly from the terminal yard, the tracks, four in number, are carried below Thirty-second and Thirty-third Streets to the East River, under which they pass in four separate tubes. The grade descending to the river is 1.5 per cent, and the ascending grades to Long Island are 0 7 and 1.22 per cent.

The new terminal station located between Thirty-first and Thirty third Streets, and Seventh and Eighth Avenues, is a truly magnificent structure, built of granite on classical lines The terminal work was carried out under Mr George Gibbs as chief engineer, to whom we are indebted for courtesies during the preparation of the present article The main entrance to the station, on Seventh Avenue, leads through an arcade forty-five feet wide by two hundred and twenty-five feet long, to the main waiting room, which, with its width of 103 feet and length of 277 feet, and clear height of 150 feet, ranks as the largest in the world. Just what these dimensions mean is shown by our front page engraving, which portrays the central portion of the New York City Hall with its tower, standing on the floor of the waiting room, with the top of its flag pole failing to reach the roof by fully ten feet. Opening out from this room are two smaller waiting rooms, each 58 by 100 feet, which are provided with the usual retiring rooms. On the same level also is the main baggage room, 450 feet in length The baggage is brought in, and carried away, through a special subway, the trunks, etc, being delivered to the track below by motor trucks and elevators. Passing through the main waiting room, the traveler will find himself on a vast concourse 210 feet wide, which extends the full width of the station and parallel with the large waiting room. From the concourse, stairs lead down to the train platforms on the track level below, which is forty feet below the street surface The concourse, which is 340 feet long, is covered by a lofty roof of light steel columns and arches and glass. Between the concourse and the tracks is a sub-concourse, sixty feet in width, which will be used for outgoing passengers only

The Thirty-third Street side of the station will be devoted to the Long Island Railroad service. It will be provided with its own entrances and exits, and the traffic will be handled independently of the western traffic.

In the design of the exterior of the station, the architects, McKim, Mead & White, endeavored to give to the building the character of a monumental entrance to the commercial metropolis of the country, which would at the same time conform to the traditional aspect of a great railway terminus. Also the station was designed to give as free a circulation as possible for the many millions that will annually pass through it. The main façade on Seventh Avenue is

composed of a Roman Doric colonnade, with columns four feet six inches in diameter and thirty-five feet high. Allowing for its much greater scale, the main entrance is comparable to the Brandenburg gate in Berlin. The main body of the building is about the same height as the Bourse of Paris, reaching, as it does, seventy-six feet above the street level. The main entrance on Thirty-second Street is at the center of this façade, and at each corner is a sixty-three-foot wide carriage drive, fronted by double columns and pediments. Midway along the Thirty-first and Thirty-third Street sides of the building are similar columns and entrances to that on Seventh Avenue.

The passenger station building, which is 784 feet long by 430 feet wide, covers some eight acres of ground, and the construction of the exterior walls, which are nearly half a mile in length, required nearly half a million cubic yards of pink granite. This and other stone work in the building ran up to a total of 47,000 tons, and to transport it from Milford, Mass., called for the service of 1,140 freights cars. Into the construction of the building there has also entered 27,000 tons of steel and 48,000 tons of brick.

The statistics of dimensions and quantities of material are of such interest that we present the following from among those supplied by the railway company:

| | |
|---|---|
| Area (10th Avenue to normal tunnel section east of 7th Avenue) | 28 acres |
| Length of trackage | 16 miles |
| Number of standing tracks at station | 21 |
| Number of passenger platforms | 11 |
| Total excavation required | 3,000,000 cubic yards |
| Length of retaining walls | 7,500 feet |
| Number of lineal feet of streets and avenues carried on bridging | 4 400, or an area of about 8 acres. |
| Concrete required for retaining walls, foundations, street bridging and substructures | 160,000 cubic yards |
| Number of columns supporting station building | 650 |
| Greatest weight on one column | 1,658 tons |
| Number of buildings removed on terminal area, about | 500 |
| Boiler capacity of service power plant ultimate | 5,000 horse power |
| Total length of tunnel (2-track), Jersey to Long Island | 5.3 miles |

After passing under the East River the four tubes reach Sunnyside Yard, the terminus of the Long Island tunnel extension, which covers some 153 acres of land. It contains 73 miles of track, and has a capacity of 1,550 cars. From the Sunnyside yard there are tracks leading to the New York connecting railroad, which will form a junction with the New Haven Railroad at Port Morris.

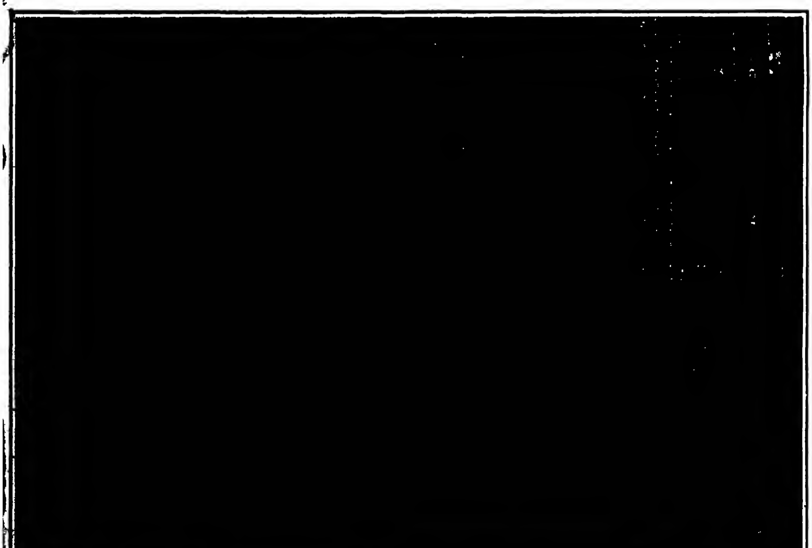
An important feature of the New York tunnel extension is its relation to the Long Island Railroad, which is subsidiary to the Pennsylvania system. It is estimated that forty minutes will be saved between Long Island points and New York city by the operation of trains through the East River tunnels to the Pennsylvania station at Thirty-third Street.

The construction of the tubes beneath the Hudson and the East rivers has been so fully described in previous issues that it will be sufficient here merely to recapitulate the principal features of this work. The tubes under the Hudson River were driven by a special shield designed by Charles M. Jacobs, who is also well known as the chief engineer of the four Hudson River tubes which were simultaneously being driven for the Hudson Company's system of rapid transit tunnels. Contract for the North River tunnels was let to the O'Rourke Engineering and Construction Company. The shields were thrust forward by twenty-four rams capable of exerting a pressure of 3,400 tons. At first, the silt and other material were removed through the doors in the front of the shield, latterly, however, the shields were pushed bodily through the material, and only about one-third of it was removed through the tunnel, being admitted through the doors in its lower face. The cast-iron lining of the tunnel is twenty-three feet interior diameter. The interior is lined with two feet of concrete making the finished interior diameter of the tunnel nineteen feet. The weight of the cast iron lining, with bolts, is from 9,609 to 13,127 pounds per linear foot of tunnel. The weight of the finished tunnel with the heavier lining, when concreted up and equipped, is 31,469 pounds per lineal foot. The weight of the silt displaced, per linear foot of tunnel, is 41,548 pounds. The weight of the tunnel with the maximum train load is 41,869 pounds per linear foot.

Thanks to the very able and efficient engineering staff, the excellence of the contractors' equipment, and the harmony with which all concerned entered into the task of driving these tunnels, the work was carried through practically without a hitch, and considerably faster than the most sanguine expectations. The driving of the tunnels beneath the East River, which was in charge of Alfred Noble, Past President of the American Society of Civil Engineers, was done by S. Pearson & Son, the contractors, of London. Because of the great variety and difficult nature of the material through which the tubes passed, much trouble was experienced at various times with blowouts, but ultimately these difficulties were mastered and the tubes pushed through to successful completion.

In addition to the many millions the Pennsylvania Railroad is spending on the four tunnels under the East River, and the station and terminal in Manhattan, all of which will greatly benefit Long Island, the Long Island Railroad is increasing its own facilities in all directions, so as to adequately care for the larger traffic which will result from the completion of the tunnels. The contemplated works will necessitate an expenditure on the Long Island system of more than thirty million dollars. The new service will include a six track line from the mouth of the tunnels to Woodside 2½ miles, one mile of 8-track road, Woodside to Winfield, two miles of 6-track road, Winfield to Glendale cut-off, and 4½ miles of 4-track road thence to Jamaica. Trains will run from Thirty-third Street, Manhattan, to Jamaica in 18 minutes, to Garden City in 34 minutes, to Mineola in 34 minutes; to Far Rockaway in 33 minutes, to Flushing in 16 minutes, and to Great Neck in 26 minutes.

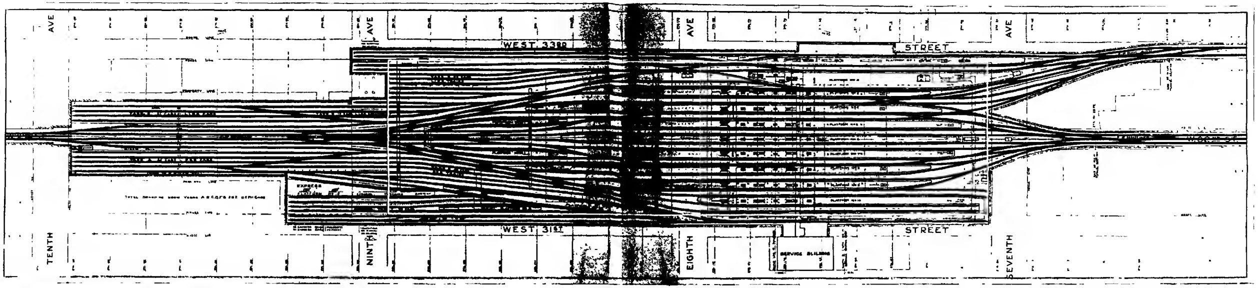
We will close by giving some of the startling statistics of population which in the judgment of the Pennsylvania Railroad Company fully warranted the enormous outlay involved in the great works which the company has undertaken. The population included within a circle of nineteen miles drawn from the City Hall in Manhattan as a center, was in 1890 3,326,998, in 1900 it had increased to 4,612 153 and in 1905 it had grown to 5 404,638. It is estimated that by 1913 the population of this territory will be about 6,000,000 people, and in 1920, 8,000,000. The railroads that have their termini on the western bank of the Hudson River carried nearly 59,000 000 people in 1886. In 1890 they carried over 72 000,000, in 1896 more than 94,000,000, and in 1906 they carried about 140 000,000 people. The significance of these figures was fully considered by the Pennsylvania Railroad, and the vast works they have undertaken are thought to be fully justified by the present and prospective growth of travel within the areas affected.



From the waiting room ([illegible] feet by [illegible] feet) the passengers enter the concourse ([illegible] feet by [illegible] feet) from which they descend by stairways to the arrival and departure platforms below

Interior view showing the concourse and the station platforms.

COMPLETION OF THE PENNSYLVANIA RAILROAD TUNNELS AND TERMINAL STATION.



The whole of this area, which [illegible] city blocks, was first cleared of 500 city houses and then excavated to an average depth of 40 feet below street level. The easterly half, between Seventh and Eighth Avenues, is covered by the station building. The whole yard [illegible] miles of track. There are [illegible] standing tracks and 11 platforms. [illegible]

PLAN OF THE HUGE SUB-SURFACE STATION YARD OF THE PENNSYLVANIA TERMINAL, MANHATTAN ISLAND

This stupendous structure, the largest of its kind in existence, covers an excavation out of which the engineers blasted some 3,000,000 cubic yards of rock. This portion of the terminal, whose floor is 40 feet below the street, contains the 21 tracks and platforms, and into it open the tunnels from New Jersey and Long Island. The superstructure, or that portion seen in this engraving, contains the waiting rooms, restaurant, [illegible] rooms, and the general offices of the railroad. The frontage is 430 feet on the avenues and 784 feet on the streets.

BIRD'S-EYE VIEW OF THE SUPERB STEEL AND GRANITE TERMINAL STATION OF THE PENNSYLVANIA RAILROAD ON MANHATTAN ISLAND

# HANDY MAN'S WORKSHOP

## HOW TO BUILD A HOUSEBOAT FOR $300.

BY FREDERICK E. LORD

The proposition of spending a summer afloat is one which appeals to many persons fond of the water, but the cost of a yacht large enough to accommodate comfortably a family for a protracted period is prohibitive to the majority, therefore people swelter ashore in hot and uncomfortable hotels, and snatch such enjoyment from the water as chance and circumstances permit

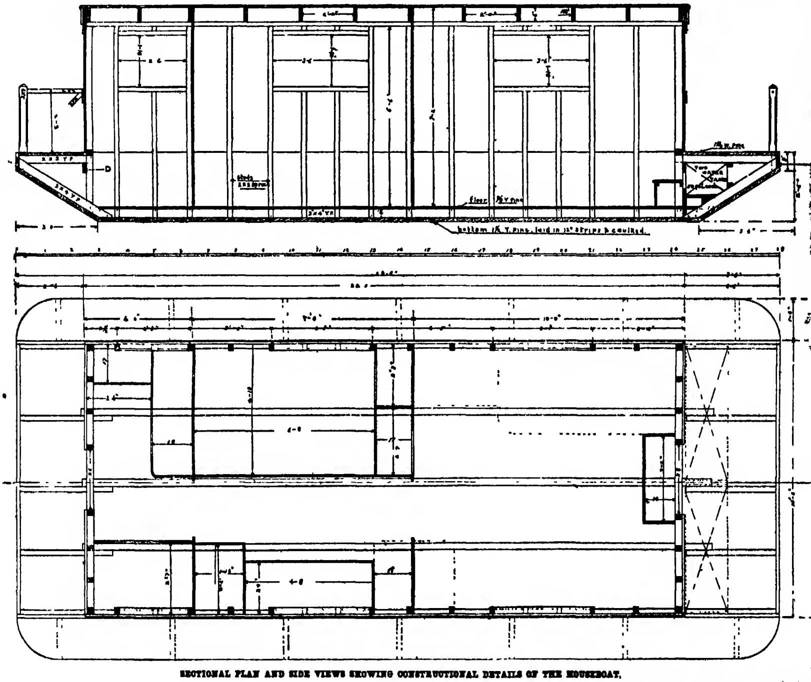
during the summer season under equally comfortable conditions. The cost of the boat would vary, according to whether it was built by amateurs and how elaborately it was constructed and fitted up A moderate price shipbuilder should build this boat complete with toilet and water tanks for five hundred dollars. As the boat is very simple in construction amateurs should be able to build it for about three hundred dollars. At a small additional cost an awning could be rigged over the house-top, thereby providing a fine, large, cool lounging space.

For those interested in building such a boat themselves the following hints on construction may prove useful

The first step in construction is to prepare the ground and build the sides and bottom of the hull The ground should be prepared by driving posts and using stringers and blocks so placed that the hull may rest during construction on an absolutely level plane By doing this a level and plumb line can be used to get the house and its compartments built plumb and true After the building foundation is prepared, start by

so that they touch on the inside and are open about ⅛ inch outside. This is to allow the caulking to be driven in and to prevent its being pushed clear through to the inside. In putting the hull together use large galvanized iron boat nails about 4 or 4½ inches long. The corner log, A, should be fastened to the sides with ¼ inch galvanized iron rivets, and the bottom planking should be fastened to both log and sides. Be careful that the planking lies perfectly flat and true before fastening, otherwise leaks will surely develop, which are hard to stop. Paint should be applied and a few threads of cotton laid along the edge of the sides to help make a water-tight job. After the bottom is on three 3 x 4-inch yellow pine stringers, C, should be fitted and nailed from the underside of the bottom. Carry these stringers up to the ends as shown in the plans. This gives us the bare hull, and we can now proceed with the house frame and small decks at each end

It might be well first to call attention to the two water tanks that are shown in the drawing. If these are to be put in it is well to do it now, otherwise some



SECTIONAL PLAN AND SIDE VIEWS SHOWING CONSTRUCTIONAL DETAILS OF THE HOUSEBOAT.

A solution of the problem of living cheaply and comfortably afloat is found in the houseboat Such a life offers many charms and advantages It is generally cooler on the water, and the air is fresher and better being free from dust and land smells. Bathing is always "on tap," and the entertainment of friends is accompanied with more charm and privacy than in a crowded summer hotel If the locality becomes tiresome the houseboat can be towed to another harbor for a few dollars and there is no packing of trunks or tipping of servants when getting out of town.

The plans herewith shown represent a small houseboat capable of accommodating four or five persons comfortably for a very moderate price It would cost four persons fifty dollars a week at an average-priced summer hotel This amounts to six hundred dollars for three months, without extras. The boat shown here could be built for less than that Then at the end of summer it could easily be sold for more than half its value or kept for another year In any case there would be a very large saving over living ashore

getting out the sides. These are of 1½ inch yellow pine, laid three strakes to a side As the depth of the hull is 30 inches the sum of the three planks should be 28½ inches to allow for the thickness of the bottom. The sides are held together by temporary strips of wood screwed to them. When thus secured fasten on the lower inside edges a yellow pine corner log 2 x 4 inches as shown in the cross section plan at A The object of this is to stiffen the edge and afford extra nailing surface for the bottom planks Now set up the sides in their proper places on the building foundation and be very careful to see that they are perfectly plumb and level, otherwise the whole structure will be crooked. Nail three or four strips across the bottom to hold it in place and then put in the end pieces B of the hull. These are of 1½-inch yellow pine Next put on the planks which extend from the end pieces to the bottom These planks, as well as the bottom ones, are of 1½ yellow pine, and about 12 inches in width. Proceed to put on the bottom by beginning at both ends and working toward the middle. Plane the planks

of the deck beams and deck cannot be laid, and it is more trouble to put them in later They should be of 1-16-inch galvanized iron and fitted with filling plates to come flush with the outside of the deck. The supply pipes can be run under the cabin flooring before it is put down.

The next members to put up are the stiff beams to take the weather boarding of the house. The beams are of 2 x 3-inch spruce. They should be cut into lengths of 6 feet 11 inches. Jog them over the corner log, A, and securely nail them to it. Fasten them to the side of the hull with stout galvanized iron nails, care being taken to get several very good fastenings in the lower side plank. The spacing of these beams will vary on account of the positions of the windows and partitions. The way to do this is to put up, first, all the beams that come at window openings and partitions and then space up equally the intervening beams. The construction plan shows the dimensions and position of the beams. A sill, C, of 2 x 3-inch spruce, is now laid on top of the beams and fastened thereto.

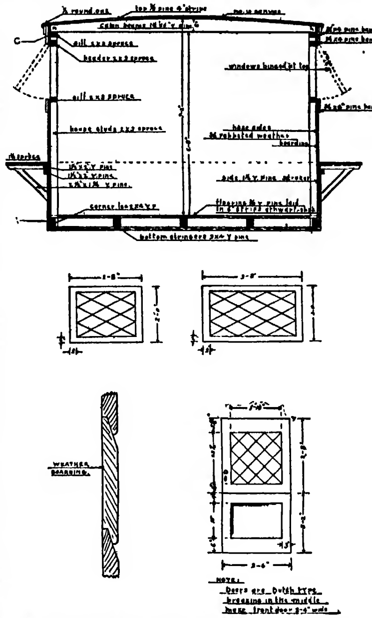
securely Put in the headers and sills for the windows and the studs immediately under them.

Proceed to finish the decks. Run 1½ x 3-inch yellow pine stringers across the end studs 4¼ inches below where the top of the deck will come. Use 3 x 3-inch yellow pine deck beams, seven to a deck, including sides, and securely nail to the stringer and end board of the hull. A deck of 1¼-inch white pine may then be laid in about 10-inch widths or less, and after being well painted covered with No 10 canvas. As the run boards on either side of the hull will serve conveniently as a staging for building, it may be well to put them on. The boards themselves are of 1¼-inch spruce planks fastened to 1½ x 2 yellow pine cleats spaced seven to a side, as shown in the plans. They are supported by 1¾ x 2½ yellow pine braces, securely fastened to the hull and jogged into the cleats.

The roof beams should next be put up. These are of 1¼-inch spruce, 6 inches deep at center and 3 inches over sills. This gives a crown of 3 inches, just enough to shed water The beams are spaced 2 feet on centers except where it may be necessary to vary them slightly so that they may serve as a backing for the partitions.

It is now in order to board up the sides. Use ⅞ x 6-inch rabbeted boards of the type shown in the section Start from the bottom and lay out the widths, as shown in the plan, so that they will come right for the finishing bands. Nail each board to every stud with two nails, and countersink and putty the heads The sides are now ready for the finishing bands and window trim' Commencing at the corners put on the vertical trim of ⅞ inch white pine 6 inches wide, and also the door trim Then the horizontal band under the windows and the strake at the upper edge of cabin, which should be 8 inches deep and finally the second band at cabin top and the window trim, both 4 inches wide All the foregoing should be of ⅞-inch white pine The trim at the window openings should be set back so that a shoulder is created by the studs and sills to form a rabbot for the window The cross section plan will show this The windows are hinged from the top and swung outward, as indicated.

Proceed to finish up the cabin roof by planking it over with ⅞ inch white pine boards laid in 4-inch widths and having a tongue and groove with a beaded edge underneath for a finish in the cabin Paint the top well and cover with No 10 canvas laid in a single piece It can be obtained in widths as high as 12 feet, and it is much better to use the single piece and get rid of seams which are liable to leak. Draw the canvas over the edge of the house, and after securely fastening with copper tacks cover them up with a half round molding, as shown in the plan. The doors and windows should be 1¾ inches thick, and these plans will be sufficient to enable any one to get them out The doors are of the Dutch type that is, they open in two sections They are more handy and convenient when thus made.



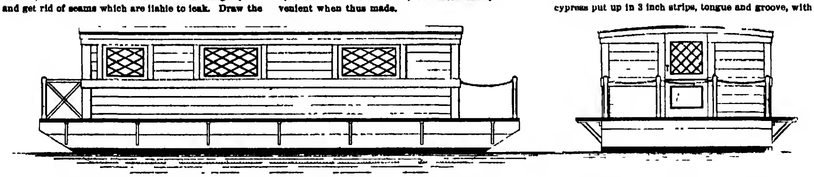
CROSS SECTION OF THE BOAT AND DETAILS OF THE DOORS AND WINDOWS.

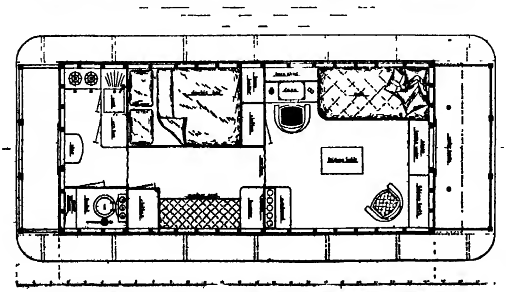
An ornamental railing fore and aft, as shown, affords safety and convenience. The after side is fitted with a rope, which can be unhooked to allow boarding the craft. This completes the hull, and we can now turn our attention to the interior

The first step is to lay the cabin flooring after painting the inside of the bottom The floor may be of ⅞-inch yellow pine, laid either in 6-inch widths or in narrower widths, with tongue and groove The former width is perhaps preferable in this case Begin at one end and plank athwartship on the stringers and corner logs. Sweep out all shavings and sawdust as you proceed After the floor is laid and smoothed up, the partitions and cabin fittings are ready to go in

The interior is arranged to provide sleeping accommodation for a mixed company of four Entering the houseboat from the after end the first compartment comprises the living room, which is turned into a sleeping room for the men at night. The doorstep has a removable tread, and is used as a locker On the right a 6½ x 3 foot couch is installed, fitted with a spring and mattress. Next to this is a desk with bookshelves above Upon the opposite side, near the door is a folding berth, shown standing on end This is built simply like a hollow box, containing an ordinary spring and mattress. It is lowered down for use and afterward up-ended and held by a couple of hooks In the opposite corner is a sideboard with glass rack above and drawers beneath to hold table linen A folding table and two or three easy chairs complete the furniture in this compartment. Of course chairs and couch should be bought, but it would be more satisfactory to make the desk sideboard and table, and this would not be very difficult if it was done simply of oak, in the mission style, and stained The next compartment is for the ladies Here a double bed is shown which may be taken from the house and installed or built in like a regular bunk with drawers underneath or left open for the reception of trunks There are two lockers at the foot, one for linen and the other opening into the sitting rooms for the men's clothes A built-in bureau is shown opposite and a window seat and clothes closet The forward compartment contains the toilet with mirror and folding wash basin on the left and the galley fittings on the right An alcohol stove is indicated along with a porcelain sink and ice-box under the dresser Stores may be carried under the forward deck The partition for the cabin divisions and lockers should be of ⅞ inch cypress put up in 3 inch strips, tongue and groove, with a V or beaded edge White paint may be used but a very nice effect is had by staining the partitions and stud beams dark green and filling in between with green burlap tacked in place and finished around the corners with a neat little molding The roof and house beams should be either white or a very light olive gray green Varnish the floor and use rugs or mats Of course the cabin sides may be ceiled over but that adds somewhat to the expense and admits of a less artistic effect A very good looking finish for the exterior is as follows After calking the bottom planks with oakum putty the seams and then give the bottom three coats of red antifouling paint Carry this up the sides for 10 inches Paint the rest of the hull black A very dark red for the weather boarding looks well Make all the bands, window trims and sash and deck railings white The decks and cabin top should have four coats of a buff color All other wood should have three coats.

The boat is moored by securing chains on either side of the hull and leading them to a common chain about 15 feet ahead of the boat Use three times as much chain as there is depth of water and a 200-pound mushroom anchor, and there need be no fear of going ashore





VIEWS SHOWING THE EXTERIOR AND A PLAN OF THE INTERIOR OF THE HOUSE BOAT.

## RECENTLY PATENTED INVENTIONS.

### Pertaining to Apparel.

COAT AND PANTS HANGER.—S. OCHMAN, New York, N. Y. This hanger is adapted to support in a smooth well formed manner the coat and either the pants or skirt of a suit of clothes. It has a supporting bar and a clamping bar coöperating with the bar, the latter being adjustably secured at one end and removably secured at its other end.

### Of Interest to Farmers.

CATTLE-GUARD.—L. T. COX, Columbia, Tenn. This invention relates to a type of cattle guards arranged on cross ties of a rail road and having yielding obstructions mounted upon the ties that hinder the free passage of cattle over the guard, and has for its object to provide a guard that is effective in service, and greatly obstruct a traverse of the guard by live stock, without injury thereto.

### Of General Interest.

BRISTLE RIM FOR ROTARY BRUSHES.—E. ABRAHAMSON, Freiburg, Breisgau, Germany. The improvements in rims consist in making the disks of sheet metal and in providing them with projections pressed out of their material which projections engage in the bristles and thus take hold of them, whereby, even when the brush rotates at high speed, any loosening of the wire as well as any shifting of bristles on the circumference of the disks is prevented. Then it is possible to use the brush until the bristles project only a few millimeters beyond the holding disks.

CARTRIDGE.—C. O. PEARSON, Hanning, Cal. The cartridge is for use in cylinder bore shot guns and like firearms, and arranged to increase the carrying capacity and to predeter mine the scattering of the shot at any distance. For this the shot is held in a container capable of separation from the cartridge casing on firing the explosive charge, the container being provided with means for retaining the shot during a portion of its flight and for turning the container over to allow the shot to scatter.

SHAVING CUP.—J. PATRONAGGIO, New York, N. Y. This cup has a receptacle at one side and a soap holder at the other side disposed above the plane of the bottom of the soap holder with which the soap is adapted to engage to hold the soap in place when the barber is making a lather by moving a shaving brush across or around the soap.

DENTIMETER.—A. D. CLARK, New York, N. Y. The purpose here is to provide a device in which the ends of the gage wire may be readily applied and detached. This is done by constructing the instrument with a head at its inner end having slots in the edges at opposite sides. The ends of the wire are passed into these slots and said ends each given a turn or two about the shank of the tool preparatory to twisting the wire loop to the tooth.

WATER METER.—J. H. CONNELL, Charleston, W. Va. In operation water enters by a throttle valve, passes into the valve chamber through an opening which is uncovered into the casing body. Force of water swings a vane until it engages and shifts a shifting bar. This swings a plate and a valve moves to cover the discharge opening. Means provide for the water to flow into the casing until it shifts the bar. The pin and slot connection between the bar and plate permits some lost motion between parts while the box spring retains the plate in swing position, and insures it a clear swing across the chamber to move a block to close and retain closed an opening.

TIGHTENER FOR DRUMHEADS.—E. M. VARKS, Norman, Okla. Among the principal objects in view in this case are to provide means for quickly tightening the heads of drums; to provide means for adjusting the tightening devices individually and for operating the same collectively; and to provide a strong, simple and efficient construction for drum bodies and head tighteners.

BABY HAMMOCK.—W. H. CONNER, Chattanooga, Tenn. This hammock may be hung from the sides of a sleeping room above the bed of the mother or out of doors on a porch or lawn, and is so arranged as to permit ready access to the occupant. One object is to readily adjust it to any height relative to its support by an improved means.

ROASTER FOR ORES.—A. J. GARVER, Clarkston, Wash. In this case the invention relates to roasters for use for ores, the more particular purpose being to produce a simple type of roaster in which the ore while heated is brought into minute contact with the air so as to completely desulfurize the ore and otherwise prepare it within a short time for smelting.

PIANO TOUCH REGULATOR.—W. S. THOMPSON and C. W. BAIR, Fort Collins, Colo. It is well known that pianos are constructed for light and for heavy touch performers. The aim of the present invention is to provide a means for regulating the touch of the action, that is the resistance of the keys to the touch of the performer, and wherein the said resistance may be increased or decreased to suit the individual.

DISPLAY FIXTURE.—W. E. TAYLOR, St. Louis, Mo. This fixture is more especially designed for advantageously displaying wall papers and the like and arranged to accommodate a number of wall papers in proper position for view and selection by a customer, and to permit of conveniently removing any one of the displayed wall papers and replacing the same by another.

VENTILATING SCREEN FOR DOORS.—I. B. SEELAY, Chicago, Ill. This improvement relates more particularly to a device comprising a screen body adapted to be movably mounted near the door, intermediate the top and bottom thereof, and to attach removably to the door when the same is partly closed, so that the ventilating openings are left at the upper and lower portions of the door way.

SIGN.—F. S. SCHAEFER and W. D. NASCH, North Yakima, Wash. This invention is an improvement in advertising signs, and has in view a sign in which the letters or other symbols on display are illuminated in either artificial or natural light, the symbols in either case presenting clear-cut reflecting surfaces in any ordinarily lighted place.

LOOSE LEAF BINDER.—T. BRAZIL-DIXSON, Milson's Point, North Sydney, New South Wales, Australia. The invention embodies a box case of two telescoping sections, screws for moving the two sections to and from each other to clamp and release the leaves, and an operating shaft operatively connected to the screws, each screw being incased in telescoping thimbles respectively carried by the opposite sides of the case, and arranged to be received in notches formed on the edges of the leaves when the latter are inserted in binding position between the plates.

DREDGING-SCOOP.—T. S. BARWIS, Vancouver, British Columbia, Canada. The intention in this instance primarily is the provision of a scoop essentially consisting of two opposed scoop members having a pivotal movement to and from each other, and which are operable to effectively claw or dig up the material preparatory to gathering it in.

### Hardware and Tools.

SEAL-LOCK.—A. A. DE A. DECASTRO, Sao Paulo, Brazil. The lock can be used with advantage for a safe, and where effective locking means is desired, but is more especially designed to be used with money remitting pouches, mail bags or anything in fact which requires a lock that cannot be tampered with without leaving clear proof of such molestation behind.

ATTACHMENT FOR REPAIR TOOLS.—W. L. DINSMOOR, Longbeach, Cal. This invention provides a heating plate for vulcanizing purposes, interchangeable with the upper or movable clamping plate on the tool. To this end the plate is preferably cast with an inner passage and has one or more burners on its outer face communicating with the passages, shields over the burners for reflecting the heat to the plate, and a lug for the reception of the clamping screw which operates to force the two jaws or clamping plates together.

### Heating and Lighting.

VAPOR BURNER.—E. B. RAYMOND, Los Angeles, Cal. The invention relates to burners adapted for the combustion of coal oil and its distillates for the generation of heat, and has for its object to provide details of construction for a burner that render it capable of vaporizing and consuming heavy coal oil, without smoking or depositing of residuum in the burner.

ELECTRIC LAMP SOCKET.—V. T. DALLAY, New York, N. Y. The present invention has in view to construct and apply a cover in a manner such that the socket ring may be revolved on the socket shell to carry the caps from over the posts and expose the binding screws thus avoiding the necessity of entirely removing the cover from the base for this purpose.

PORTABLE ACETYLENE-GAS GENERATOR.—D. A. LOVELESS, Watersmeet, Mich. The invention embodies an outer water tank, an inner carbid tank and a cover common to both removably applied, the former having bowed springs supporting the latter, having a central stem adjustably connected to the cover and provided with an enlarged pocketed portion at its lower end through which water from the water tank percolates into the carbid tank, and the cover having a conical screen for straining the gas as it leaves the generator, with the screen pointing outwardly.

### Household Utilities.

ADJUSTABLE IRONING BOARD.—J. G. KIRKPATRICK, Prescott, Ariz. In its construction the device includes a leg which rests upon the floor, and an object of the inventor is to provide means for rigidly bracing the board upon this leg, and further to provide improved means for adjusting the board to varying heights or thicknesses of the table edge.

CLOSET-SEAT.—T. G. PHILPOT, Augusta, Ga. This invention is an improvement in water-closet seats of wood. In a seat of this class it provides means for preventing the splitting of the side sections across their deflected ends and this is accomplished in the present instance by means of lugs extending from the ends of the front and rear sections.

REFLECTOR-STOVE.—J. T. RESNOR, Mercer, Pa. Mr. Resnor's invention pertains to reflector stoves, his more particular purpose being to provide a stove to be heated by gas, vapor, or other combustible aeriform body, the construction being such that the heat when produced is distributed advantageously and diffused as nearly equally as possible.

### Machines and Mechanical Devices.

PERFUME-VENDING MACHINE.—A. F. VONCH, Bensonia, Mich. This machine comprises a bulb presser for the atomizer, with check-controlled means to lock the presser against retraction in its advanced movement, automatically released as the bulb is pressed, and to lock the presser against advanced movement in its retraction, whereby the presser cannot be withdrawn until the advance movement is completed, nor be advanced after being partially retracted, which prevents the operator receiving but one spray for each check or coin.

INDICATOR.—W. D. STANTON, New York, N. Y. The object here is to provide a machine so constructed that the values thereon can be viewed from different directions when the indicator is projected into a transparent part of the register casing, and in which each indicator consists of a plurality of telescopically arranged units, thereby conserving space and reducing the size of the machine.

COMPRESSOR.—J. D. MAYHAW, Tyler, Texas. This compressor is employed in connection with ammonia, ice or refrigerating machines that compress the gas from the coils into the condenser. One object is to produce means whereby the maximum amount of gas or vapor may be compressed. Further to provide a compressor in which the heat evolved during operation of compressing gas or vapor may be utilized to dry the incoming gas.

WELL-DIGGING APPARATUS.—M. LATTA, Valentine, Neb. In the present patent Mr. Latta provides a settling chamber, and a pumping mechanism by which to exert a constant suction in the settling chamber and a suction pipe discharging to the settling chamber, and to this extent in a broad way the present invention is similar to the apparatus shown and claimed in a former patent granted to this inventor.

RUDDER.—S. B. MCNEELY, Natchez, Miss. More particularly the invention relates to a rudder which is normally inoperatively disposed in a well carried in the hull of the vessel and located near the bow, suitable means being provided for projecting the rudder into an operative position and for turning it to steer the vessel in one direction or the other.

MEAT-SLICER.—A. W. JOHNSON, New Brunswick, N. J. This improvement refers to slicers such as used for making slices from roast beef, corned beef, and similar meats. In its general construction the device presents a cradle upon which the cut of meat rests, and the frame of the device supports a knife toward which the meat is automatically advanced by the operation of the knife.

MATRIX FOR LINOTYPE MACHINES.—C. W. HASSAICH, Berlin, Germany. The invention relates to an improvement in matrices, whereby many defects are avoided. It consists in reducing the contact surfaces of the side portions to middle parts, which extend over the intaglio letters. Thereby the risk of imperfect filling of the middle parts of the composed matrices is reduced and a more perfect lock up of the composed lines is assured.

APPARATUS FOR PREPARING MATRIX SHEETS FOR THE REPRODUCTION OF WRITTEN MUSIC OR THE LIKE.—F. DOUILLET, 18 Rue Oberkampf, Paris, France. This machine is for use in printing suitable surfaces by means of suitable characters or type but it is more particularly suitable for the preparation of matrix sheets intended for use in the reproduction of written music. It is electrically operated and is provided with a controlling arrangement by which regularity in the action exercised by the type on the surface to be printed upon or stamped, is obtained automatically.

### Prime Movers and Their Accessories.

OILING SYSTEM FOR ENGINES.—G. W. FAIRFIELD, of the U. S. Navy. In the present patent the invention has reference to oiling systems for engines, and the object of the improvement is the provision of means for use in automatically oiling the wrist pin and crank pin bearings of an engine. The oil is provided in a continuous circulation.

INTERNAL-COMBUSTION ENGINE.—O. E. FREAS, Albany, N. Y. Means provide in this case for controlling the inlet and exhaust ports of four-cycle engines by fluid pressure. Both the inlet and the exhaust valves connect with auxiliary pistons mounted in auxiliary cylinders. Means are provided to open the inlet valve which remains open during the suction stroke. No cams, rock shafts, levers or mechanism operate valves from crank shaft or any other moving part of the engine. Gas pressure is utilized as sole means for operating all the valves.

HYDRAULIC-POWER PIPE SYSTEM.—C. A. COMPTON, Washington, D. C. The main object here is to provide a means by which a stream of falling water may be partially deflected in an upward direction and may be again brought into contact with the descending stream, thereby imparting to the latter increased pressure. Further, to provide a means for accomplishing the above which may be applied to any power plant having a turbine shaft and a turbine located at the bottom thereof.

### Pertaining to Recreation.

COMBINED HOBBY-HORSE AND VEHICLE.—F. W. FURMAN, Hicksville, N. Y. More particularly the invention relates to a form of vehicle or cart combined with a hobby horse, so that the person riding on the vehicle will be seated on the horse. By means of certain features, the device may serve all of the functions of an ordinary rocking-horse, or may serve the functions of a cart or ordinary vehicle, or all of the advantages of both may be combined in one.

COUNTER-HOLDER.—C. M. RAMBY, Courtenay, N. D. The intention here is to provide a holder for pool and like counters, in which the number of counters remaining in the holder can at all times be easily determined, in which the counters cannot be identified, which serves as a substitute for the ordinary "bottle" commonly used to contain pool counters, and which obviates the occurrence of certain mistakes in the use of the counters.

PUZZLE.—D. E. SMITH, Mount Vernon, N. Y. The idea in this case is to produce a means of affording amusement and interest in attempts at solving a puzzle. The invention relates to that type of puzzles which includes a ring which is apparently attached to other pieces so that it cannot be removed, but the construction is such as to enable the ring to be removed by the exercise of ingenuity, and the manipulation of the parts.

### Pertaining to Vehicles.

LOG-RETAINER.—W. DREVES and C. KELLAHER, Tomahawk, Wis. The device embodies a sill having a strap passing around each end from one side of the sill to the other, each strap having at one side of sill a dog pivoted to swing from below the upper face of the sill to upright position, and at the other side a chain latch for securing the holding chain of the opposite dog, with further means, whereby the dog at one side of the car or vehicle is locked and released at the opposite side of the car.

VULCANIZING IRON.—W. L. DINSMOOR, Longbeach, Cal. This iron is to be heated by acetylene gas from the acetylene lamp generator, and is provided with a flat and concave vulcanizing face with one or more intermediate combustion chambers, the flat vulcanizing face serving to apply the patch to inner tubes, and the concave vulcanizing face serving in a like capacity for outer tubes while the latter remain in place on the motor vehicle wheel.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

## Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th, 1909, or will be sent by mail on request.

(12221) E. S. L. asks: Have you a SUPPLEMENT or other paper that will give me a plain explanation of the principle of the radiometer? A. The explanation of the rotation of the radiometer is given in Barker's 'Physics,' page 395, in Carhart's 'High School Physics,' page 203, in Hoadley's 'Elements of Physics,' page 224, and in most of the textbooks of physics. Some one of these will doubtless be within your reach. All these agree that the blackened faces absorb heat more than the bright faces of the mica disks, and thus become hotter than the bright faces. In turn they radiate the heat more rapidly, and thus a reaction force of the nature of a pressure is produced, which causes the fly to turn just as a rotary lawn sprinkler is turned by the reaction of the pressure of the water. An iron ball heated below redness will cause the radiometer to rotate in the dark, showing that light is not necessary to produce the effect, but that heat alone is competent for the explanation of the instrument. It was at first thought that light caused the rotation, but that has been abandoned.

(12222) O. R. says: Relative to Query 12217 in issue of April 2nd, 1910, the distance of the moon—240,000 miles—is only the radius of a circle, the circumference or orbit would approximate 1,440,000. T. H.'s calculation would then work out so that the moon would subtend an angle of one-half degree, which practically corresponds with the telescopic measurements. A. In Query 12217 the writer used the radius of the moon's orbit where he should have used the diameter, and so all his calculation was wrong. Otherwise his reasoning was right, and he would have found the moon's apparent diameter to be a half degree had he not made this mistake.

(12223) C. L. W. asks: That introducing resistance into a circuit reduces the number of amperes flowing is of course plain, according to Ohm's law; the amperes being equal to the electromotive force divided by the resistance in ohms. I have also always been under the impression that resistance introduced into a circuit [illegible]

voltage of the circuit after the current had passed through the said resistance, and that this voltage would fall according as more or less resistance was introduced. The following experiment is therefore hard to explain, if this is so: We connected two 110 volt lamps in series on a 220-volt circuit, and in the opened point as shown below, after the current had first passed through the lamps, inserted a large standard voltmeter, which read 218 to 220 volts. This was repeated many times, with the greatest precautions as to connections; and also on other sources of supply, and the results were the same, in a general way apparently no drop of any appreciable extent having occurred by the passage of the current through the lamps, although of course the amperes were cut down What is the explanation of this? Much discussion has arisen over it, and the claim made that the voltage should have been reduced. A. The case of the lamps and the voltmeter as you describe it is no exception to Ohm's law The resistance was not that of two lamps in series, but of two lamps and a voltmeter which had a resistance of many thousand ohms. The current in amperes became inconsiderable because the resistance was so high, and the voltmeter registered only the voltage. The voltage would be the same as if the lamps had not been in series in the line. No amperes were flowing, or at most a very small fraction of one ampere The point is this the voltage at the end of an open circuit is the same as that anywhere along the circuit The drop between any two points of a closed circuit is proportional to the resistance between those two points. If the circuit which you show in your figure had been closed the lamps would have been lighted, showing that current was flowing, and the voltmeter would then have shown 110 volts drop between the two terminals of each lamp This is in strict accordance with Ohm's law

(12224) C A. Y says Why do not seven new gravity cells connected in series give about 7 volts after being set up and short circuited for 24 hours? I bought seven gravity cells for use in charging a 6-volt-60 A. M. P. hour storage battery, but I cannot make them give more than about 2¾ to 3 volts, although each one gives a particle over one volt, and two in series show about 1½ volts, and three in series about 1¾ volts, etc A We are not prepared to say positively why you have so low a voltage for your battery in series. If we saw the battery, we might be able to tell what is required. We suspect that you kept it on short circuit too long and that the zinc sulphate solution is saturated If the colorless liquid reached down nearly or quite to the coppers, this is the case You should take out some of the zinc sulphate from the top and fill in with water again.

(12225) J B says: I have a magnet needle belonging to an old surveyor's compass which has lost its magnetism. Will you please tell me through Notes and Queries how to renew it? A The best mode of magnetizing a compass needle is to draw it across the pole of an electromagnet. If you use the north pole of the magnet, draw the south end of the needle last from the north pole After drawing the needle from the north pole of the magnet several times reverse the needle and draw it across the south pole of the magnet, drawing its north end last from the south pole of the electromagnet A compass needle may probably be magnetized sufficiently by drawing it in the same way across the poles of a horseshoe magnet If you have not the apparatus for doing this, take the needle to the electric light station and ask the engineer to magnetize it for you.

(12226) B B says 1 What is brake horse-power? A The brake horse-power of a machine is the power it can exert as determined by means of a brake upon the axle or pulley of the machine You will find an article upon this mode of measuring power in our SUPPLEMENT No. 1787, price ten cents. 2. What is meant by ultra violet? A The ultra violet region of the spectrum is the part which the eye cannot perceive because the waves are too short to affect the retina The longest waves below the red do not affect the retina and are also invisible To these the name "infra-red" is given The colors of the rainbow run from the red through yellow, green, and blue to violet. Beyond the violet the eye can see nothing But there is a very large region there which can be explored by other means, such as the photographic plate or the fluorescent substances.

(12227) C. H. W says. I would like to hear through your columns a satisfactory explanation of the following. Take an ordinary flat-iron and a gasoline torch such as is used by plumbers, etc. Lay the flat-iron on its side, and turn the full force, of the torch against the face of the iron. Water will now condense and collect in large drops on the face of the iron, and will continue to collect until the iron gets hot enough to evaporate the water A. All natural atmospheric air contains a certain proportion of moisture, i. e., water evaporated and in suspension. Most gasoline also contains a percentage of water Consequently the gasoline vapor in a torch or engine contains moisture, being a mixture of air and gasoline. Upon the hot gas or flame impinging upon a cold iron or other surface, the moisture is condensed just as the moisture in your breath, otherwise invisible, is condensed into little drops of water on a cold window pane when you breathe upon the latter.

## NEW BOOKS, ETC.

THEORETICAL PRINCIPLES OF THE METHODS OF ANALYTICAL CHEMISTRY. Based Upon Chemical Reactions. By M G Chesneau. Translated by Azariah Thomas Lincoln, Ph.D., and David Hobart Carnahan, Ph D. New York, The Macmillan Company, 1910 8vo.; 184 pp Price, $1.75.

The book takes up the influence of the physical state of precipitates upon their purification by washing, the theoretical principles involved in methods based upon irreversible reactions, as well as a study of methods based upon reversible actions. In Chapter III we have the study of principles involved, according to the calorimetric theory, in reversible actions, in Chapter IV the presentation of the electrolytic theory of these reactions, and in Chapter V a comparison of these two methods. The next chapter deals with the general processes which produce complete precipitation in double decomposition, and inversely which cause precipitates insoluble in water to become soluble. In the final chapter the principles established in the preceding chapters are applied to some particular methods based upon double decomposition

THE EVOLUTION OF WORLDS. By Percival Lowell. Pp xiii + 262, 12 plates and 56 text cuts. New York, The Macmillan Company, 1909 $2.50 net.

To those who are familiar with Prof Lowell's books on Mars, the cosmogony which he outlines in this latest work of his must come as a surprise. In his earlier works he pinned his faith to the *La Place* nebular hypothesis, now he practically adopts the Moulton Chamberlin "planetesimal" theory, without calling it by that name, which seems like to a reversal of himself. Mr Lowell's proneness to see markings upon other planets than Mars finds expression once more in this volume, for we note that he still insists upon the appearance of dark spots on Venus, spots which he regards as fixed features, and which no other astronomer has ever seen Contrary to the usual supposition that Venus is surrounded by a dense atmosphere, Mr Lowell holds that its atmosphere is of the thinnest, and that the planet's brightness is due to the attenuated atmosphere The sections on Mars reiterate his well known views on the habitability and gradual decay of that planet The book is written in Mr Lowell's usual style, a style which is most attractive to the lay reader but which is characterized by occasional chasing of the odd word, and therefore affected at times. For good, popular scientific reading, even though it presents only the very personal views of its author, the book is certainly to be commended.

HANDBUCH FÜR HEER UND FLOTTE By George von Alten. Berlin, Leipzig, Stuttgart, Vienna Deutsches Verlagshaus Bong & Co

The two installments of the "Handbuch für Heer und Flotte" which lie before us begin with "Bristol" and end with "Carnotscher Kreisprozess." Among the articles which deserve to be particularly mentioned are those on Bronze, "Brücken" (an excellent exposition of the various types of bridges employed for military purposes) "Brasilien" (a good geographical and military consideration of the biggest country in South America), "Burg" (in which various forms of mediaeval strongholds are considered)

HEALTH PROGRESS IN THE ADMINISTRATION OF THE WEST INDIES. By Sir Rubert W Boyce, M.D, F.R.S New York E. P Dutton & Co, 1910. 8vo, 328 pp Price, $3 50

The epitomized record of the progress of sanitation and sanitary administration in the West Indies is the outcome of a visit which the author paid to the West Indies in 1909 in order to investigate an epidemic of yellow fever which was present in the colonies of Barbados at the time. While making the investigations on the subject of yellow fever in Barbados, he was requested by the Governor of the Windward Islands and the Governors of Trinidad and British Guiana to prolong his stay and visit their respective territories and report upon the health conditions obtaining in these colonies. The results of the author's experiments as described in the present volume is of value not only to the medical and business man, but also to the tourist who wishes to reside in or visit these beautiful colonies. The book is beautifully illustrated with interesting half-tones.

THE PLANT CELL By Harold A. Haig, M.B, B. S Lond London: Charles Griffin & Co, Ltd Philadelphia, J B. Lippincott Company, 1910 12mo, 207 pp.

The author's aim has been to deal with the study of structural and physiological botany from a biological standpoint, in which the working substance of a cell, namely, the protoplasm, is given the first place in importance, the subsequent changes which are produced in form, function, etc., being looked upon as being due to the sole agency of the protoplasm, influenced by the various physical and chemical stimuli which may be brought to bear upon it. This method of dealing with the cell, whether animal or vegetable, has been found, in the writer's experience, to be a rational and useful one when such a wide subject as biology is first approached by the student. The section on cell division has been presented in rather full detail, on account of the great importance attached nowadays to cytological phenomena in which the nucleus is involved. With regard to the illustrations, a *few photomicrographs* have been inserted, and these give a rather more realistic aspect to one or two of the more difficult sections, such as those on embryology and nuclear division

THE UTILITY OF ALL KINDS OF HIGHER SCHOOLING An Investigation By R. T Crane. Chicago, 1909 8vo., 331 pp Price, $1 00 net.

This edition gives further results of the author's investigation of the utility of academic or classical education for young men who expect to pursue a commercial or industrial career The following subjects have been investigated and studied Technical Education in Manufacturing, Technical Education in Civil Engineering, Technical Education in Electrical Engineering, Agricultural Colleges Manual Training in the High Schools, Business Education Medical Education, Scientific Education; Rural Schools.

ON THE TRAIL OF WASHINGTON By Frederick Trevor Hill. Illustrations in color by Arthur E. Becher New York and London D Appleton & Co, 1910 276 pp, 8vo Price, $1.50 net.

For more than a century Washington was exalted as a model of manners and morals—and portrayed as a prig, he was idealized as a hero—and rendered unreal, he was glorified as the father of his country—and denied all human fellowship with his kin, he was invested with every virtue, and divested of all virile character That he survived in the affections of his people is the best demonstration of his true greatness Of recent years, however, there has been a notable effort to depict the man as he really was, a man with good red blood in his veins, good common sense in his head, good kindly feeling in his heart, and a good honest laugh This humanizing of Washington has been the work of eminent editors, historians, and collectors, and their investigations during the past twenty years have virtually revealed Washington to Americans for the first time. It is to place before readers, young and old, the results of this modern research that the writer retells the story of Washington in these pages

THE DESIGN OF CONDENSING PLANTS. By F W Wright. London The Technical Publishing Co, Ltd., 1909 203 pp, 12mo, illustrated Price, $1 50

Considerable attention has been devoted during the past few years to the subject of *condensing equipment for steam plants*, and scattered throughout the technical press and in the published transactions of engineering societies, are to be found a number of valuable papers embodying the results of careful and extended observations and experiments by able investigators So far, however as the author knows, there was no book devoted exclusively to a consideration of the various problems involved, and in many of the standard text books on the steam engine, the references to the question of condensing are very brief The pages are a modest attempt to supply the lack in a volume of such dimensions and price that it should be within the reach of all who are interested in the subject.

SCIENTIFIC LIVING FOR PROLONGING THE TERM OF HUMAN LIFE. The New Domestic Science, Cooking to Simplify Living and Retain the Life Elements in Food By Laura Nettleton Brown New York The Health-Culture Company, 1910 284 pp, 12mo. Price, $1 00

A great truth is emphasized in this book, namely, that in the ordinary processes of cooking the organic elements become inorganic and food values are destroyed. This dietetic idea is most important, and it is claimed by the author that when generally known and made practical it will restore the racial vigor as nothing else can, free woman from the slavery of the cook stove and become a large factor in the solution of the servant problem. The volume is thoroughly sensible and enlightening, original without being cranky radical without being faddish withal, practical plain and entirely helpful

HOVEY'S HAND BOOK OF THE MAMMOTH CAVE OF KENTUCKY A Practical Guide to the Regulation Routes, With Maps and Illustrations By Horace Carter Hovey, D D, F G S A Louisville John P Morton & Co, Inc, 1909 64 pp., 16mo. Price, 25 cents.

The writer is well known to the readers of the SCIENTIFIC AMERICAN, having written many articles on the subject of caves and caverns for its columns. The present book may be regarded as an excellent guide to the Mammoth Cave and should be in the hands of all those who may think of visiting this unique wonder

ENGINEERING THERMODYNAMICS By C F Hirshfeld, Professor of Power Engineering, Cornell University New York: D Van Nostrand Company, 1910. 16mo boards, 78 pp Price, 50 cents.

The following pages represent an attempt to develop the principal thermodynamic properties of gases and of vapors in such a manner that the underlying principles may be clearly recognized. It is thought that a thorough understanding of the laws developed in the text will, on the one hand give a working knowledge sufficiently extensive for most engineering purposes, or on the other will enable the student to more easily follow the generalized and complicated cases considered in the large standard works on the subject

SHELL-FISH INDUSTRIES By James L Kellogg, Professor of Biology in Williams College New York Henry Holt & Co 1910 Illustrated by half tones and original drawings. 8vo, 361 pp Price, $1 75 net

This fills a much needed gap in the literature of natural history, or what may be called applied natural history It covers the classification propagation, and distribution of shell fish For the person who eats oysters, clams or scallops, there is information on their structure life histories and habits. A chapter is devoted to shell fish as collectors and carriers of disease organisms. The oyster culturist will find the life history of bivalves from the egg period to the time when they reach the market, a comparison of various culture methods, and a description of oyster fields in various parts of the world

HALLEY'S COMET By David Todd, M A, Ph D, Professor of Astronomy and Navigation and Director of the Observatory, Amherst College New York The American Book Company, 1910 8vo, paper Price, 50 cents.

The major portion of this pamphlet on comets is a reprint of the comet chapters of Prof Todd's "New Astronomy" The reprint is preceded by an introduction in which the usual information on Edmund Halley and the manner in which he applied Newton's law of gravitation to the comet of 1682 is described as well as the circumstances of the comet's present return On the whole it must be stated that of all the cheaper works which have been published to meet the popular demand for a simple account of Halley's comet Prof Todd's is the most accurate and the most informing

THE PASSION PLAY OF OBERAMMERGAU Translated from the German text, with a Historical Introduction By Montrose J Moses New York Duffield & Co 1910 12mo, 118 pp Price, $1 50 net.

The volume before us is printed on delightful light weight paper so that we have no hesitancy in recommending it as an ideal text for visitors who are going to have the supreme pleasure of witnessing the Passion Play The text which is sold in Oberammergau and Munich is apt to be bad and very dear and it is really good economy to take along a book like the present volume with its black faced readable type The writer of this book review had the pleasure of seeing the Passion Play in 1890 he therefore thinks that possibly he is competent to review a book on this subject There are a number of important features. The list of *dramatis personae* are contrasted with various years such as 1890 and 1900 The history of the Passion Play is given with valuable notes referring thereto The four ancient texts of the Oberammergau Passion Play are then examined The description of the play house etc, follows together with the statement issued by the Burgomaster showing the ratio of expense to receipts. This shows that in 1890 the salaries of the 747 players were only $18,000 or an average of $24 each which is not very large pay for an all summer's work which interferes very materially with their regular pursuits This shows that the Passion Play as regards the members is not very much of a money making scheme There is however a considerable amount made each year the Passion play is produced by those who have concessions of various kinds, such as the photograph concession The text itself of the play is admirable and is followed by the best bibliography of the subject which we have ever seen

THE ROMANCE OF MODERN CHEMISTRY A Description in Non Technical Language of the Diverse and Wonderful Ways in Which Chemical Forces Are at Work and of Their Manifold Application in Modern Life By James C Philip, D Sc Ph D Philadelphia J B Lippincott Company, 1910

For a book frankly intended for popular reading, it must be confessed that the author has succeeded in producing a most readable account which ought not to exact too much intellectual effort on the part of the reader in endeavoring to follow the development of chemistry and to discover some of its modern achievements. The subjects discussed are the following Dawn of Chemistry Alchemy and the Philosopher's Stone Nature's Building Material Invisible Substances and How We Know of Their Existence Elements with a Double Identity, Metals, Common and Uncommon Where Two Metals are Better than One, Acids and Alkalis Natural Waters and What They May Contain Chemical Changes which Produce Light and Heat How Fire is Made Nature's Stores of Fuel More About Fuel Flame, What is It? Explosions and Explosives Below Zero Chemistry at High Temperatures Chemistry of the Stars, Chemistry and Agriculture, Sugar and Starch, Fats and Oils, How Man Competes with Nature; The Adul

toration of Food The Value of the By Product, Valuable Substances from Unlikely Sources, Chemistry and Electricity, Some Interesting Facts About Solutions, From Solutions to Crystals, Great Effects from Small Causes How Trifling Observations Lead to Great Discoveries

COMETS Their Origin, Nature, and History By Henry W Elson New York Sturgis & Walton Company, 1910 Illustrated, 54 pp Price, 50 cents

In this little book Mr Elson has presented in readable and simple form the more elementary facts relating to comets. In an introductory chapter on the solar system and stars he traces the relation between Newton's discovery of the law of gravitation and the Copernican theory of a heliocentric planetary system. With some regret we notice that he illustrates his explanation of gravitation with the old fable of Newton's apple for which Voltaire is responsible and which has long been discredited No attempt whatever is made to explain the physical constitution of comets or to give any explanation of tail formation or a summary of recent spectroscopic study, omissions which may have been intentional because of the difficulty in setting forth the more difficult aspects of cometary phenomena in a short, popular essay

THE INTERPRETATION OF RADIUM Being the Substance of Six Free Popular Experimental Lectures Delivered at the University of Glasgow, 1908, by Frederick Soddy, M A New York G P Putnam's Sons, 1909 8vo, 256 pp, 31 illustrations Price, $1 75 net.

The substance of half a dozen popular lectures given at the University of Glasgow are here presented in book form The matter has been rewritten so as to secure continuity of treatment The subject is presented in non technical language and is intended to be of service to workers in other fields of investigation as well as to the general public The recent important discoveries of Prof Rutherford and his experiments with Dr Geiger in counting the number of alpha particles expelled by radium have been added to the book. Altogether the work will be found most interesting to the general reader

NAUTICAL SCIENCE In Its Relation to Practical Navigation. Together with a Study of the Tides and Tidal Currents By Charles Lane Poor, Professor of Astronomy in Columbia University New York and London G P Putnam's Sons, 1910 8vo, 31 illustrations, 11 plates, 320 pp Price, $2

Astronomy finds its most practical application in navigation However, many a navigator knows very little astronomy as most of the astronomical matter which is necessary for the guiding of his vessel is presented to him in the form of tables and formulæ which he accepts without inquiring into their mathematical significance The present work attempts to explain in non technical language and without the use of complicated mathematical formulæ the fundamental facts and principles that form the basis of all navigational methods. A large part of the book is devoted to an explanation of tides and tidal currents, and their causes, giving the recent researches of Dr Harris which show that the tides of each ocean basin are practically independent of those of the rest of the world.

LUDWIG DARMSTAEDTERS HANDBUCH ZUR GESCHICHTE DER NATURWISSENSCHAFTEN UND DER TECHNIK Von Professor Dr L. Darmstaedter Berlin Verlag von Julius Springer, 1908. 1262 pp Price, $4

It would be difficult indeed to exaggerate the importance of this chronology of inventions and scientific discoveries The names of the distinguished editor and his collaborators are in themselves sufficient guarantee of the accuracy of the work and the painstaking labor which its compilation involved For all that no one can possibly realize how arduous must have been the task of preparing this work without having actually handled the book itself Its 1200 odd pages are packed with concise and yet lucid statements of the principal scientific and mechanical discoveries year by year beginning with 3500 B C and ending with 1908 An admirable index facilitates reference

PHYSICAL AND COMMERCIAL GEOGRAPHY A Study of Certain Controlling Conditions, of Commerce by Herbert Ernest Gregory Albert Galloway Keller and Avard Longley Bishop Boston and New York Ginn & Company, 1910 8vo. 269 pp Price, $3 00

From the time when they are first offered to the child for study the facts of production and trade have been listed rather than interpreted The books which have dealt with these matters have been prevailingly of a statistical nature and the study of what they have had to give has too often reduced itself to a mere mnemonic exercise And yet there are behind the facts of trade as behind all facts certain principles about which they can be grouped and which serve to lend them life and meaning, and it is interpretation rather than arbitrary memorizing which is of educational importance The present work which is intended to be used as a text book, is based on a consideration of this idea. It is seldom that we see the authorship of a book split up into three parts, the result, however, in this case appears to have been beneficial, and it has undoubtedly added much to the value of the book that three professors of science have co-operated in its production It is a most excellent book which can also be added with advantage to the library

SCHOOL ARCHITECTURE. A Handy Manual for the Use of Architects and School Authorities. Compiled by William George Bruce Milwaukee Johnson Service Company, 1910 18mo., 385 pp Price, 50 cents.

The present edition embodies a decided advance over the former efforts and a practical departure in plan of presentation. In scope it is extended so as to include every phase of scientific school-house planning and to embody the latest and best thought and experiment on the subject. In presentation an entirely new plan has been adopted Instead of presenting all subjects in topical form, arranged in alphabetical order, it has been planned to arrange the subjects with a view of giving them logical sequence and continuity The ready reference feature which was emphasized in the former editions is preserved in an ample index and table of contents.

INTERNAL LUBRICATION OF STEAM ENGINES By T C. Thomsen, M Soc D.C.E. London. The Technical Publishing Co, Ltd., 1910 12mo 97 pp. Illustrated Price, $1 00

This book has been written in the hope of it proving to be of some assistance to mechanical engineers directly interested in the satisfactory running of steam plants, to improve the internal lubrication of their engines, and if they have troubles, to give such information as will be useful in determining the nature of the trouble and the probable cure Designers of steam plants may also find points of interest and value in scheming means for applying cylinder lubricants, and the best way of distributing them to the internal surfaces needing lubrication Very little is said about the chemical and physical properties of cylinder lubricants, or about the various methods employed in distilling and refining, the main points under consideration being the mechanical side of the question

TAVERNS AND TURNPIKES OF BLANDFORD, 1733-1833 By Sumner Gilbert Wood. Blandford, Mass. Published by the author, 1908 $2 00

In no small degree the tavern and turnpike story shapes and describes the social development of a town like Blandford, so rich in fact and incident, so the author concluded to publish this monograph before running the larger risk always attaching to the publication of the conventional local history, the circulation of which is necessarily narrow Should this little volume meet with such response as to warrant the venture, it is the author's intention to follow it with another on the "Homes and Habits of Ancient Blandford." The book is a monument of industry and many of the illustrations which are given show bits of old New England

FREIGHT TRANSPORTATION ON TROLLEY LINES By Charles S Pease. New York McGraw Hill Book Company, 1909 16mo 62 pp. Price, $1 00

Generally speaking the freight business of a traction road is more profitable than its passenger service, while with electric traction lines this relation will not obtain, therefore, the subject of goods transportation is worthy of the close study of the company intending to follow as far as may be expedient the practice of the great trunk lines. A monograph on the subject is therefore far from being out of place The whole subject seems to have been treated in an admirable manner Special attention is given to stationery

CEMENT AND HOW TO USE IT Edited under the supervision of William A. Radford Chicago The Radford Architectural Company, 1910 8vo 369 pp Price, $1 00

The present volume has been prepared in response to numerous requests for a treatise written in simple non technical English which will serve the purpose of a plain working guide to the seclusion of cements and aggregates, the purpose of proportioning and mixing concretes, and the rules obtaining in the many forms of construction to which it has shown itself so well adapted Throughout the volume constant emphasis is laid on the product as distinguished from the theoretical mode of treatment. On account of the intimate relation which cement and concrete now bear to every branch of construction, the present volume will be of great practical value not only to concrete workers but to all other craftsmen engaged in the various trades of the building industry, such as carpenters, steel workers, plumbers, engineers, and others.

THE DESIGN AND CONSTRUCTION OF OIL ENGINES. By A. H Goldingham. New York Spon & Chamberlain, 1910 16mo. 260 pp Price, $2.50

This work has been written with the intention of supplying practical information regarding the kerosene or oil engine, and in response to frequent requests received by the writer to recommend such a book. Whilst many works have been published on the subject of gas engines, some of which refer to or describe the working of the oil engine, no other book, it is believed, is devoted entirely to the oil engine in detail. The work, it is hoped, will be found useful to the draftsman, the engine attendant, as well as to those who own or are about to instal oil engines. The classification of vaporisers has been adhered to as made some few years ago, and a representative engine with each type is described.

FOOLISH QUESTIONS. By R. Goldberg. Boston Small, Maynard & Co., 1909. 18mo, ill. Price, 50 cents.

The present volume is a reproduction of cartoons which were originally published in the New York Evening Mail

AUF VORPOSTEN IM LEBENSKAMPF Biologie der Sinnesorgane, I-Fühlen U-Hören. Von Dr H. Dekker Stuttgart Kosmos Gesellschaft der Naturfreunde. 93 pp.; 33 illustrations.

This is a popularly worded treatise on the biology of the sense organs, devoted chiefly to tactile sensations or peripheral sense organs.

MATTER AND SOME OF ITS DIMENSIONS. Washington, D C. Woodward & Lothrop. 99 pp

SELECTED SHOP PROBLEMS. By George O Seaton Peoria, Ill. The Manual Arts Press. 12mo; 16 plate and 15 pages of text.

GILLETTE'S INDUSTRIAL SOLUTION WORLD CORPORATION By Melvin L Severy Boston The Ball Publishing Company, 1908. 8vo. 594 pp Price, $1.50.

## Legal Notices

# INDEX OF INVENTIONS

**For which Letters Patent of the United States were Issued for the Week Ending May 3, 1910,**

**AND EACH BEARING THAT DATE**

[See note at end of list about copies of these patents.]

(Continued on page [illegible].)

TWO NOVEL MOTOR SLEDS.

(Concluded from page 396.)

touches the ground, appears to stand still, while the sleigh slides over it. This is the motion that actually takes place, for the top of the chain travels forward at twice the speed of the sleigh. It will thus be seen that in reality the lower part of the chain in contact with the ground constitutes a surface over which the vehicle itself can move.

The driver has his position on a box behind the engine, which seat forms a receptacle for tools, spare parts and other accessories. That the vehicle has great climbing power has been conclusively proved, for it will ascend steep banks of earth and ride over serious obstacles easily and without any appreciable diminution in speed.

Although this sleigh can carry a party and full equipment, its actual function is to act as a tractor for the haulage of ordinary sledges, the trailing vehicles carrying the loads. Upon completion by the builders, the tractor was taken to Norway by Capt. Scott, and submitted to some exacting trials on snow covered Lake Fefor and the tumbled country in its vicinity, where the conditions were somewhat analogous to those prevailing around the south pole. Heavily laden trailing sledges were hitched on to the tractor and numerous journeys were made among the Norwegian ice fields. The vehicle proved itself fully capable of withstanding rough usage, and Capt. Scott expressed his complete satisfaction with the results achieved.

Very different from this sled in design is one which has lately been put to a series of severe running tests over all kinds of ice and snow in the district of the Silian Lake, Sweden. The accompanying photograph of the motor sleigh was taken in the Easter days of this year, after the above-mentioned tests had been carried out.

The design differs from that of other automobile sleighs in the driving mechanism. The sleigh is propelled by two driving wheels, each fitted with a number of steel paddles between which an elastic frame is fixed. This simple construction thus combines the advantages of a paddle wheel and the Canadian snow shoe, having the propelling capacity of the former on fixed ice and snow surfaces, and the supporting and friction capacities of the latter on loose snow. The flexibility of the frame tends further to prevent the snow from clogging by expelling it from the paddles. The driving wheels run in the tracks made by the sleigh runners, and thus tend to make a good contact surface for the paddle wheels. In case the snow is not compressed enough by the runners, the paddle wheels sink by their own weight into the snow, and compress it sufficiently by means of the frame. The paddles engage with the compact snow by cutting through the crust as knives, and work on account of their breadth, against such a large wedge of the frozen snow surface, that an effective counter pressure is obtained which would otherwise be impossible if the driving wheels were, for instance, provided with spikes instead of paddles. The sleigh is in this instance driven by a 6-horse-power double-cylinder air-cooled gasoline motor. The motor sleigh illustrated is designed to serve only as a traction engine, to which any kind of sleigh can easily be attached or detached within a few minutes.

It is of course easy to make the motor sleigh as self-contained as an ordinary automobile, and the electrically-driven forerunners of this sleigh were successfully built in this way.

The motor sleigh is governed by means of a very ingenious and reliable steering device for remote hand operation. The power required for steering is transmitted from the operating hand-wheel through flexible steel tubes to the motor.

In the tests a speed of 24 miles an hour over a smooth ice surface was attained. When traveling over the snow and ice-covered roads, which were in a very bad condition on account of the prevailing thaw, a speed of 10 miles an hour was attained, the total weight drawn being over one ton. During a running test of several consecutive hours, the average speed was 19 miles an hour.

The inventor is a Swedish engineer, Mr. H. Hakanson.

## An Industrial Laboratory for the Improvement of the Incandescent Lamp.

Although the establishment of a research laboratory by a large manufacturing organization is not a novelty, the inception by such an organization of a laboratory which has for its object the development of science rather than the improvement of some industrial commodity is probably without precedent. For that reason, Mr. E. P. Hyde calls attention in a recent number of Science to the new physical laboratory of the National Electric Lamp Association, even though it is still only in a formative state. The object of this laboratory is scientific, the specific purpose being the development of those branches of science with which the art of lighting is closely associated. The fundamental idea which has prevailed in the organization of the work is the proper co-ordination of physics and physiology, the proper co-operation of the physicist, the physiologist and perhaps the psychologist.

The organization of the laboratory is proceeding with this idea as the foundation. The development contemplates no sharp distinctions among the different divisions of the work. The problems to be investigated, however, group themselves roughly into three classes, and therefore require, in order to insure the proper attention to each, a threefold division in the organization. The three groups of problems to be investigated may be classified as (1) those that have to do with the production of luminous energy, (2) those that have to do with the utilization of luminous energy, and (3) those that have to do with the effects of luminous and attendant radiation.

Under the first class will come the investigation of the laws of radiation, and of the radiating properties of matter. The problems in this class are purely physical and the corresponding division will be intrusted to a competent physicist.

Under the third class will come the investigation of the effects of light and the attendant radiations on the eye, on the skin and on microscopic organisms. The problems in this class are physiological, and the corresponding division is under the charge of a trained experimental physiologist.

Intermediate between these two classes of problems (the first and the third) which are distinctly different, there is another (the second) which forms the connecting link. Touching on one side the physical production of light, and on the other the physiological effects of light, this intermediate division of the work will embrace most of the scientific problems peculiar to illuminating engineering. Investigations of the absorbing, reflecting and diffusing properties of matter, the measurement of light, i. e., photometry, and the study of the complex phenomena of color and color sensation, properly come within the scope of this department of the work.

## Scientific Cider Making.

Messrs. Alliot and Gimel recently presented a paper to the Académie des Sciences concerning the good results obtained in the production of cider by washing the apples with an oxidizing solution. Inasmuch as cider is the usual beverage of the populations of the north and west of France, its manufacture should concern hygienists as well as technicians. In many cases the quality of the product is much inferior to what it should be were the process well carried out. The washing of the apples is indispensable to free them from the impurities which they carry, but we must also take account of the defective quality of the water which is available in many cases. The authors' previous re-

(Concluded on page 408.)

(Concluded from page 407)

searches showed them that oxidising agents could be used to advantage, and they experimented with hydroxyl, ozonised water, and hypochlorites of soda and of lime in solution in the water which is used for the washing Used in the proportion of 40 to 60 centigrammes per liter of water (0 4 to 0 6 per 1,000), which is more than enough to destroy pathogenic germs of the human species, they find that hypochlorite of lime has a good influence on the activity of the pectase, which is the coagulating diastase of the pectic matters of the juice of apples. Where the fruits carry much impurity they should first be washed in ordinary water before immersing them in the oxidizing solution The tests carried out first in the laboratory in 1905 were pursued in the cider-making districts during the seasons of 1907-8 and 1908-9, and they led to the following conclusions First, the addition of hypochlorite of lime in the above proportions according to the state of purity of the fruit, assure the purifying of the doubtful waters as to bacteria for the present purpose The juice of the fruit thus treated is found to clarify rapidly The coagulation of the pectic matter is always well carried out and we have formed an abundant brown surface layer This assures the stability of the cider with time in this respect. The diastases, especially the maloxydase, are eliminated by precipitation, so that we avoid the principal cause of darkening of the cider It is also found that the hypochlorite has a favorable selective action on the *Saccharomyces mali* and a destructive action on *the anaerobic germs*, and it thus solves practically and simply the problem of a pure fermentation By adding to this treatment the method of repeated under-drawings, we can obtain cider which will keep much longer, and this is of interest *for* producing bottled cider There is no harmful matter introduced by the present process. Comparative analysis of cider made from treated and from untreated apples shows a marked advantage in favor of the former.

### Military Kites.

Kites, as well as dirigibles, captive balloons, and aeroplanes, may be made serviceable in military scouting, and their simplicity makes them especially valuable. Furthermore, they can be employed with any velocity of wind between 16 and 66 feet per second, whereas the use of a captive balloon becomes difficult if the velocity of the wind exceeds 26 feet per second Experiments recently made at Boulogne by Capt. Saconney show that it is quite practicable to carry two persons by means of a large kite The kites used in his experiments were of the Cody type with four sustaining planes and with triangular stabilizing wings In this method of construction each rectangular cell is strengthened by diagonal rods of bamboo to which the stabilising wings are attached The apparatus consisted of a series of kites connected together, for the purpose of supporting the cable, and of a second series of kites attached to a very light carriage, which moved along the cable, and from which the car or basket was suspended

Kites can nearly always be used at sea and on the coast. They are simpler and less expensive in every way than balloons and they are also strong and easily repaired. These qualities should make them valuable for many purposes in military and especially in naval operations.

A wireless telegraphy station near Berlin claims to have established a record in combined overland and sea transmission of wireless messages The station recently succeeded in maintaining wireless communication with a Woermann liner during the entire voyage from Hamburg to the Cameroon The greatest distance signaled was 6,600 kilometers (over 4 000 miles) Although messages had to pass over the Alps the Algerian tableland, and the Adamana Range, communication was, it is stated, effected with astonishing ease.

# Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

## BUSINESS OPPORTUNITIES

WANTED by a firm of Sheffield, England, Steel Manufacturers, a firm to sell First Class Quality High Speed Steel and Superior Quality Files. Only applications from those who can command business will be considered. For further particulars apply Box 2116, T. B. Browne's Advertising Offices, 163 Queen Victoria Street, London, England.

Inquiry No. 8918.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

## PATENTS FOR SALE.

FOR SALE.—Collapsible step ladder, patented Feb. 1908, and Feb. 18, 1908. Patent numbers 879,361 and 880,344. Address P. O. Box 83, Brooklyn, N. Y.

Inquiry No. 8987.—Wanted, the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

## FOR SALE.

FOR SALE.—A number of Corundum, Alundum and Craigleith Stones, sizes ranging from 25" to 31" dia., 1¼" to 1" face. Some of the wheels are straight face others beveled. These are offered at very attractive prices and those interested may secure prices and inventory by communicating with the Bausch & Lomb Optical Co., Rochester, N. Y.

Inquiry No. 9014.—For manufacturers of machinery, supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

## TYPEWRITERS.

REAL REMINGTON $18.75.—One machine only in new localities to secure desirable agent. Special agents prices supplied on all makes of typewriters. 4 ribbons $1.00. Standard Typewriter Exchange, 23 Park Row, New York.

Inquiry No. 9016. Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

## LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9023.—Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

## MISCELLANEOUS.

CHEMICAL analysis, investigation and research work. Processes devised. Correspondence invited. J. F. Dunnigan, Chemist, Milburn, N. J.

Inquiry No. 9029.—Wanted catalogues and all information on machinery for braiding straw in manufacturing straw hats.

## SITUATIONS WANTED

PRACTICAL mechanic is open for position of responsibility either to assist manager, superintendent or inventor. 20 years experience. A. X., Box 773, N. Y.

Inquiry No. 9038.—Wanted, the address of the Chipman Electric Purifying Co.

## SALE AND EXCHANGE.

FOR SALE.—Engine lathe. Our regular $78.00 lathe complete, with a face plate, two centers, wrenches and a full set of change gears to cut all size threads. Price only $45.00. L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9043.—Wanted the address of Farney Safety Razor Co.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9066.—Wanted to buy machinery to manufacture seed corn racks.

Inquiry No. 9075.—Wanted to buy small weather vanes, such as can be used as ornaments on lightning rod tops. Aluminum preferred.

Inquiry No. 9076.—Wanted, the address of parties in Canada who could make a safety razor.

Inquiry No. 9077.—Wanted, the address of manufacturers that make small articles of wood, such as checker boards, etc.

Inquiry No. 9078.—Wanted, the address of manufacturers of sewer pipe, made of fiber and asphaltum, suitable for laboratory use.

Inquiry No. 9080.—Wanted the address of parties manufacturing paste-making machinery.

Inquiry No. 9082.—Wanted, the address of firms manufacturing small beer brewing plants, from 25 to 100 gallons a day.

Inquiry No. 9090.—Wanted manufacturers of suspender and supporters supplies, also patent adjustable bachelor buttons.

Inquiry No. 9092.—Wanted, the address of some firms who manufacture permanent lamp wicks.

Inquiry No. 9094.—Wanted address of The Thomas Arithometer Company, also Burkhart Arithometer Company.

Inquiry No. 9096.—Wanted, the address of manufacturers of spiral welded pipes, possessing great strength.

Inquiry No. 9097.—Wanted, address of makers of impulse water wheels.

Inquiry No. 9098.—Wanted, name and address of the manufacturers of the canister.

Inquiry No. 9099.—Wanted, address of manufacturers of machinery for making wire cables.

Inquiry No. 9101.—Wanted, addresses of manufacturers of a dip or magnetic needle, for exploring for iron ore.

Inquiry No. 9104.—Wanted, addresses of manufacturers under the name of A. O. Co. Standard.

Inquiry No. 9107.—Wanted, addresses of manufacturers of small emery files (pieces of emery in the shape of a file).

Inquiry No. 9109.—Wanted addresses of the manufacturers of the Dual Desk Clock.

Inquiry No. 9113.—Wanted name and address of the manufacturers of the Russell Patent Automatic Ink Well.

Inquiry No. 9114.—Wanted name and address of manufacturer of the Auto Lantern Globe. Fits all lanterns.

Inquiry No. 9115.—Wanted a machine for making rat files, similar to Wm. Mitchell's C. & J. wide and Waverly files.

Inquiry No. 9117.—Wanted names and addresses of the manufacturers of pedometers.

Inquiry No. 9118.—Wanted, a treatise for a machine designed, built upon the principle of the Maxim silencer, recently brought out for use on rifles.

Inquiry No. 9119.—Wanted, name and address of the manufacturer of Berlin bullet-proof cloth.

Inquiry No. 9120.—Wanted, the address of the Ideal Fuel Feeder Co.

Inquiry No. 9121.—Wanted, manufacturers of cut stencils for fancy work, sofa pillows, etc., and oil colors and brushes for same.

Inquiry No. 9124.—Wanted, name and address of a company in Germany making a machine to manufacture a cement and asbestos shingle and building lumber.

Inquiry No. 9127.—Wanted, address of L. Demigny, manufacturer of a family ice machine for $10.00.

Inquiry No. 9132.—Wanted, manufacturers of a gasoline traction engine with a hoisting attachment; in other words, the machine will be used as a portable stump puller to pull sassafras roots, used in making oil of sassafras.

Inquiry No. 9134.—Wanted, a small hydraulic motor, capable of giving about one horse power with a water power of 45 lbs. per square inch.

Inquiry No. 9135.—Wanted, name and address of manufacturers of the Parshall Compressed Air Ice Machine.

Inquiry No. 9136.—Wanted, the name and address of a skunk raising farm.

Inquiry No. 9137.—Wanted, a device that will braid leather strips for horse whips.

Inquiry No. 9138.—Wanted, the address of manufacturers of machines capable of forming a number (15 or more) of pieces of paste about 25 mm. x 40 mm. x 6 mm., made of lead oxide and sulphuric acid, and placing them into a frame having a separate compartment for each piece, the space between each piece and the next being all round 4 mm. The process could be somewhat similar to biscuit making.

Inquiry No. 9139.—Wanted, the name and address of some manufacturer of a coffee mill run by water motor.

Inquiry No. 9140.—Wanted, manufacturers of disc records for gramophones that use a sapphire point instead of a steel needle.

Inquiry No. 9143.—Wanted, name and address of the manufacturers of an air mattress.

Inquiry No. 9144.—Wanted, manufacturers of machinery for making soda water tubes, commonly known as straws.

Inquiry No. 9145.—Wanted, to buy machinery to load blasting caps or detonators.

Inquiry No. 9146. Wanted address of firms engaged in die cast work.

Inquiry No. 9147.—Wanted manufacturers of machinery for making manilla rope and all kinds of ropes from fibre of century plants, such as maguey agave, henequen maguey or any such fibres.

Inquiry No. 9148.—Wanted manufacturers of machinery for weaving bags of fibre also manufacturers of machinery for separating fibres as above mentioned from their respective plants.

Inquiry No. 9149.—Wanted, manufacturers of machinery for roasting coffee for small and large industries.

Inquiry No. 9150.—Wanted, manufacturers of machinery for the manufacture of French heels for ladies' shoes.

Inquiry No. 9151.—Wanted, manufacturers of cocoanut oil machinery.

Inquiry No. 9152. Wanted, the address of the Graham Safety Lamp Filler and Ventilator.

Inquiry No. 9153.—Wanted, name and address of manufacturers of a knotless clothes line.

Inquiry No. 9154. Wanted name and manufacturers of a newspaper vending machine.

Inquiry No. 9155. Wanted, the address of manufacturers of an electric milking machine.

Inquiry No. 9156.—Wanted the name and address of manufacturers of a rust proof oil, known as Caochouc Oil.

A printed copy of the specification and drawing of any patent in the foregoing list or any patent in print issued since 1863, will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co., Inc. 361 Broadway New York.

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list. For terms and further particulars address Munn & Co., Inc. 361 Broadway, New York.

## How to Make a 100-mile Wireless Telegraph Outfit

In the following SCIENTIFIC AMERICAN SUPPLEMENTS, the well known wireless telegraph expert Mr. A. Frederick Collins, describes clearly and simply without the aid of mathematics the construction of a 100-mile wireless telegraph outfit. Complete drawings accompany his descriptions.

The design and construction of a 100-mile wireless telegraph set is described in SCIENTIFIC AMERICAN SUPPLEMENT 1605.

The location and erection of a 100-mile wireless telegraph station is described in SCIENTIFIC AMERICAN SUPPLEMENT 1622.

In SCIENTIFIC AMERICAN SUPPLEMENT 1623, the installation and adjustment of a 100-mile wireless telegraph station is fully explained.

The adjustment and tuning of a 100-mile wireless telegraph outfit is discussed in SCIENTIFIC AMERICAN SUPPLEMENT 1624.

The theory and action of a 100-mile wireless telegraph outfit is explained in SCIENTIFIC AMERICAN SUPPLEMENT 1625.

The management and operation of ship and shore stations is clearly set forth in SCIENTIFIC AMERICAN SUPPLEMENT 1626.

These six articles constitute a splendid treatise on the construction operation and theory of wireless telegraph instruments. The complete set will be mailed to any address for 60 cents.

SINGLE NUMBERS WILL BE MAILED FOR 10 CENTS

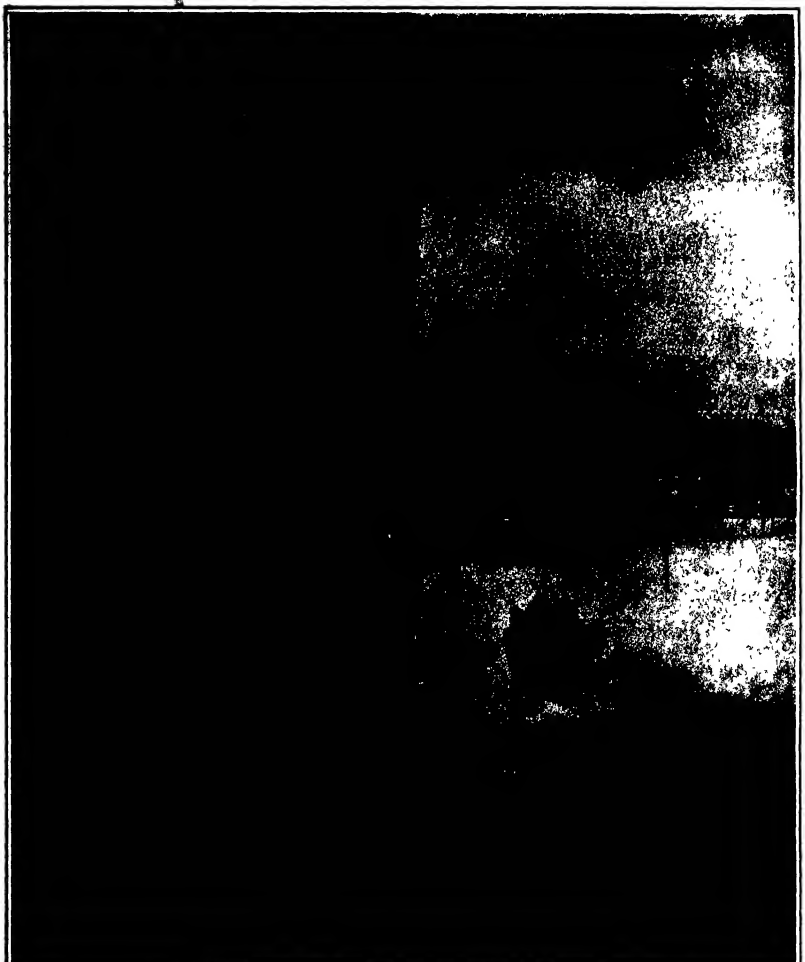
A POPULAR ILLUSTRATED WEEKLY OF THE WORLD'S PROGRESS

Vol. CII.—No. 21. ESTABLISHED 1845. | ★ NEW YORK, MAY 21, 1910 ★ | 10 CENTS A COPY $3.00 A YEAR



Oil was struck at 2,200 feet depth. The stream rushed forth with such violence that it blew off the top of the derrick and rose over 200 feet above the ground, falling in a widely scattered shower of oil rain. The well has continued to pour forth oil at the rate of 42,000 to 45,000 barrels per day, forming the huge lake seen in the foreground of the picture.

THE LAKEVIEW GUSHER, CALIFORNIA.—THE MOST PROFITABLE OIL WELL IN THE WORLD.—[See page 410.]

[illegible] ... per year extra.

THE SCIENTIFIC AMERICAN PUBLICATIONS

Scientific American (established 1845) ... $3.00 a year
Scientific American Supplement (established 1876) ... 5.00
American Homes and Gardens ... 3.00

The combined subscription rates and rates to foreign countries, including Canada, will be furnished upon application.
Remit by postal or express money order, or by bank draft or check.
MUNN & CO., Inc., 361 Broadway, New York

NEW YORK, SATURDAY, MAY 21st, 1910

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

## NEW SKYSCRAPERS FOR OLD

UNDER modern industrial conditions things are done in a big way and often with a strong dash of the spectacular. But the city dweller, albeit he is daily confronted with the unusual and the unexpected, must confess to some measure of surprise on learning that a modern skyscraper 300 feet in height, and but a dozen years old, is to be torn down to make way for a new structure which is to be several stories higher, and—more "up-to-date," if you please. To the conservative European, the ruthless demolition of a building that must have cost over a million dollars, and is still entitled to be called new, will appear, no doubt, as another instance of our national vice of extravagance. But it is not so. The Gillender building is being razed in accordance with a certain industrial doctrine, which has been found to give most excellent economical results, namely the doctrine of the "scrap heap," according to which we believe and have proven in a thousand ways that so soon as the march of improvement or development renders it certain that there is more profit in scrapping an existing machine, plant, or building, and replacing it by another more efficient or of greater capacity, it is a matter of sound business policy to send that machine to the "junk heap," or turn the "wrecking gang" loose upon that building.

The policy is purely utilitarian—brutally so if you like—a mere question of dollars and cents, but it is a good business policy nevertheless, and, in reality, has been one of the most powerful factors in bringing about the present phenomenal industrial development of the United States.

Your old-world engineer or architect, with perhaps a stronger flavor of sentimentalism, hesitates to sweep a faithful servant so remorselessly out of the way. He will point with pride to his forty-year-old locomotive with its million-mile record of service, and he will add wing to wing and another story or two to a building, if this be possible, rather than raze to the foundations and build from the ground up. It is a case of each to his choice, though there are not wanting many indications that British engineers are beginning to realize the value of the scrap heap, and apply the principles which it implies in the development of their industrial enterprises.

The Gillender building, which stands at the northwest corner of Nassau and Wall streets, in this city, is a sixteen-story steel-frame office building which was completed in 1898. The construction was first class, the foundation being put down by the pneumatic process, and the steel frame thoroughly braced to resist wind and racking strains. From street to cornice the sixteen stories extend for a height of 241 feet, and the picturesque three-story tower above brings the total height to about 300 feet. The exterior of the building is faced successively with granite, limestone, and terra cotta. Examination has shown the structure to be in as good condition to-day as when it was put up, and engineers and architects will be greatly interested as the steel frame is uncovered, to observe how much, if any, oxidation of the inclosed steel work has taken place. In all probability, judging from the condition of the steel work of other composite buildings which have been demolished, such, for instance, as the Pabst building, removed a few years ago to make way for the New York Times structure, no rusting will have occurred that is worthy of mention. The removal of the Gillender building, while it will not probably bring to light any new facts regarding the behavior of inclosed steel columns, will strongly establish the conviction (should everything be found intact) that if the steel work be thoroughly painted at the mill, at the shops, and before it is inclosed in the building, it is absolutely proof against rusting and will remain intact and serviceable as long as the inclosing walls and roof endure.

Outside of rusting, there is no other known agency that tends to shorten the life of the steel frame of the modern skyscraper. Exploded long ago was the theory of the fatigue of metal. Simple statical stresses, or even dynamical stresses of frequent repetition, do not necessarily shorten the life of steel structures. It is only when these repeated stresses approach the elastic limit that the strength of the metal is imperiled—and in the modern skyscraper no such conditions exist. Certain imaginative magazine writers to the contrary notwithstanding, the visitor to New York five hundred or a thousand years hence will find the skyscrapers of to-day in perfect condition, provided, of course, that the doctrine of the scrap heap above referred to has not called for their demolition.

## OUR NAVY AS A NATIONAL INSURANCE.

AT the recent launch of the "Florida," as the great ship was starting down the ways, one of the crowd was heard to remark: "What a shameful waste of public moneys it seems when we think that this $10,000,000 ship may never be employed in the work for which she was built, and that if she ever gets into a fight, she may be sent to the bottom within a few minutes of the opening of an action." The remark was characteristic of much that is being said and written on the subject of the wastefulness of modern armaments. Taken by itself it would seem to be convincing, but if we look at the question broadly, and with that just sense of proportion which is necessary to a correct estimate of the value and meaning of things, we shall see that such talk is the purest sophistry. The costliness of a battleship must be judged in relation to what it stands for and the work which it is intended to do. In the last analysis the "Florida" is one element in an economical system of national insurance, designed to protect both the lives and the property of the ninety millions of inhabitants of the United States.

The true test of the question of the extravagance of naval expenditures is to determine the ratio that they bear to the money value of the property which they protect. The following estimates of expenditures, which have been furnished from Washington, show that the first cost of the ships of the navy, as they float to-day, is roughly $400,000,000, while the current annual expense of their maintenance is about $44,000,000. The cost of maintenance last year, including pay of officers and enlisted men of the navy and marine corps, pilot dues, provisions, clothing, ordnance equipment, medical and machinery stores, including coal, water and other incidentals, amounted to nearly $38,000,000. The cost of repairs to the hulls, machinery, and equipage of the vessels amounted to more than $6,000,000, making the combined expense of preserving peace on our shores nearly $44,000,000.

The amount involved covers the expenses of all the various types of our ships of war, which include battleships, armored cruisers, cruisers, scouts, the torpedo flotilla, monitors, gunboats, supply ships, hospital ships, colliers, converted yachts, tugs and receiving ships.

As an example of the heavy expense of maintaining a big ship of war, we may take the battleship "Connecticut," which was the flagship of the Atlantic fleet during the last year. The pay of the officers and enlisted men of the navy and marine corps attached to the vessel and the expenses incidental thereto amounted to nearly $800,000. This did not include the cost of the necessary repairs.

The home fleet, or the vessels attached to the Atlantic side of the country, last year consisted of sixteen first-class battleships, which were divided as follows: six of the "Connecticut" class of 16,000 tons, five of the "Georgia" class of 14,500 tons, the "Idaho" and "Mississippi" class of 13,000 tons each, the "Missouri" and "Ohio" of 12,500 tons each, and the "Wisconsin" of 11,500 tons. The average cost of keeping a vessel of the "Georgia" class in commission and on active service, which did not include repairs, was nearly $680,000, while that of the "Idaho" and "Mississippi" class was nearly $530,000 each. The average cost of the "Missouri," "Ohio" and "Wisconsin" ran close to the $600,000 mark for all three. While these figures will vary for the same ships in different years, the cost of maintenance will not change much from year to year for the same class. The total cost of keeping these sixteen battleships of the Atlantic fleet in active service last year amounted to more than $10,500,000. It costs just about as much to keep an armored cruiser in active service as it does a first-class battleship, as is evidenced by the fact that the ten armored cruisers which were in commission last year cost the United States $7,000,000. Of these cruisers in commission, six were of the "West Virginia" 13,680-ton class, and the other four of the "Montana" 14,500-ton class.

With the increase in size of the battleships, there is a corresponding outlay for pay of the personnel, stores, maintenance, and repairs. The latest battleships to be placed in commission, the "Michigan" and "South Carolina," each of 16,000 tons displacement, will require crews of more than 50 officers and more than 800 men each. After these are ready, the "Delaware" and "North Dakota," each with 20,000 tons displacement, and each requiring 53 officers and 878 men, will be placed in commission. These will be followed by the "Florida" and "Utah," each of a normal displacement of 21,835 tons and each requiring 60 officers and 954 men, while the 26,000-ton "Arkansas" and "Wyoming," contracted for last fall, will each require a crew of 85 officers and over 1,000 men.

Now there is no denying that these expenditures, considered by themselves, are enormous, but when they are measured up against the vast national wealth in whose interest they are incurred, they sink into positive insignificance—and our navy is seen to be the least costly, as it certainly is the most effective, institution in that scheme of national government which is designed to protect the lives and property and to further the happiness of the people of the United States.

If the above seems to be a strong statement, it is capable of easy proof. The latest estimate of the wealth of the United States available in the Bureau of Statistics is that of 1904, made by the Census Bureau, which put the total for that year at $107,104,[illegible],917, or $1,310 per capita. The 44 millions which the navy cost last year may be regarded as the cost of insurance against damage and loss of that 107 billions, and as such, it represents a premium of only four one-hundredths of one per cent. If we include the interest on the capital cost (400 millions) of the existing fleet, the premium is only six one-hundredths of one per cent, while the cost of the "Florida" (10 millions), which loomed so large in the eye of the captious critic at her launching, dwindles to one one-hundredth of one per cent of the wealth of the country.

## THE UTILIZATION OF SOLAR HEAT

IF the heat of the sun's rays were entirely converted into mechanical energy, it would furnish more than two horse-power for each square yard of surface exposed to the sun, but in practice it is difficult to utilize solar heat. Attempts were made in France by Mouchot and Tellier in 1871 and in Sweden by Ericsson in 1883. Mouchot and Tellier used a conical mirror to concentrate the rays upon a boiler containing water or other volatile liquid, but the mirror was costly and it gave only one horse-power for 12 square yards of reflecting surface. Tellier, in 1885, caused the sun's rays to be absorbed directly by a lamellar boiler, containing a thin layer of water or more volatile liquid, such as ammonia or carbon disulphide. The same method has been recently employed by Shuman and Willsie in America. Shuman employs the steam generated to drive a low-pressure turbine. The boiler is constructed upon the principle of a greenhouse, i. e., on the property which glass possesses of transmitting the sun's rays but stopping the return of thermal radiation from the interior. The boiler is a large vat coated with pitch and containing a layer of water three inches deep. An apparatus of this sort was operated in Philadelphia in 1907-1908.

Willsie also employs a lamellar boiler covered with glass, but the water heated in this boiler is used to vaporize the more volatile liquid, ammonia or sulphur dioxide, the vapor of which performs a closed cycle. In California an apparatus of this kind, with a boiler of 120 square yards of heating surface, furnished a mean power of 15 horse-power. Willsie estimates the cost of the apparatus at about $1.50 per square yard and calculates that it should absorb, at the 34th parallel of latitude, about 4,000 calories per square yard per day. With these data about 50 square yards would furnish one horse-power and would cost $80. For a large plant of 400 horse-power, however, the total first cost per horse-power would be doubled. The cost of operation is about 3/5 cent per horse-power-hour.

---

In experiments made at the agricultural station of Lausanne, Switzerland, for the purpose of determining the effect of potash fertilizers upon natural meadows, two neighboring fields having almost identical soils of glacial marl, showed a marked difference in effect and, very curiously, the soil of the field that had yielded the larger crop was found, after harvest, to contain more potash than that of the other field. This remarkable result has been traced to the influence of drainage. The better drainage of the field which yielded the larger crop promoted the circulation of air and water in the soil, favored the assimilation of soluble nutriment, and caused the roots to extend to a greater depth and utilize a larger volume of earth. This example shows that the fertility of a soil cannot always be determined by chemical analysis alone.

## ENGINEERING.

**Reinforced concrete** continues to widen the range of its application. The Western railroads are preparing to build this summer long stretches of reinforced concrete snow sheds. These will not only be stronger than the present timber structures, but they will be entirely safe from the menace of fire

**The independent gasoline-driven** railroad motor car, which we have frequently illustrated in this journal, is growing in favor A new car, 70 feet in length, recently left the shops at Omaha for the Buffalo, Rochester and Pittsburg Railroad This is the seventy-fourth car of the type to be turned out from these shops, and it is the sixth car to be built for service east of the Mississippi River

**The ever-increasing** weight of Western passenger trains is being met by a steady growth in the size and power of the locomotives. The Chicago, Milwaukee & St Paul have recently turned out of their shops two types of six-coupled simple locomotives, with cylinders 23 inches by 28 inches, one of which has 69-inch drivers and a tractive effort of 31 900 pounds, and the other 69-inch drivers and a tractive effort of 500 pounds.

**An electrically**-operated pile driver is described in a recent number of the Electrical Review and Western Electrician The apparatus, which is of English make, is provided with a revolving frame and swivel leaders. Instead of a mechanical device for gripping the monkey, an electro-magnet is used, the top of the monkey being planed off smooth to provide a good contact surface An electric motor is used for operating the hoisting crab The circuit of this motor includes the magnet, and the switch for the latter is attached to the crab

**An important** paper on oils used for switches and transformers was recently read at the Manchester session of the Institution of Electrical Engineers. It was pointed out that very little attention has been paid to the quality of the oil used in this way, and that any impurity in the oil would reduce its resistance to a flow of electric current, also that the specific resistance at different temperatures varies with the grade of the oil Careful investigation of this subject was urged with a view to obtaining oils of standard resistance values.

**In a recent** lecture before the Engineers' Club in New York, Mr Elmer A Sperry, the electrical engineer, demonstrated with a working model the value of his "active" gyroscope If the ordinary, or "passive" gyroscope be applied to ships, the vessel must roll some 2½ degrees before the counteracting influence is exerted In the new type the least tendency toward a roll sets in operation a governing device, consisting of a smaller gyroscope, which starts the larger gyroscope, and thus secures an instant and absolute stability Mr Sperry believes this new type will provide the gunner with a perfectly stable platform

**America** will be represented this year in European yacht racing by the large and powerful two-masted schooner, "Westward," which has been built by Herreshoff for A S. Cochrane of the New York Yacht Club The "Westward" is the largest American racing schooner yet sent across the Atlantic She is of 197 tons gross, as compared with the "Ingomar," of 142 tons, also built by Herreshoff, which a few years ago made a brilliant record in English and German waters She will meet the big German schooners "Meteor" and "Germania," and probably one or two English built schooners of less size, but of proved speed and ability

**According** to A. A C Swinton, the first flight of a model aeroplane propelled by steam is to be credited to the Hon Charles A. Parsons of turbine fame, who in 1893 built an aeroplane with two 11-foot wings and a tail, and drove it with a steam engine whose cylinder was 1¼ inches diameter by 2 inches stroke, steam being supplied by a boiler 2½ inches diameter by 14 inches long, in which steam was generated at 50 pounds pressure by a spirit lamp The whole apparatus, including aeroplane, engine, and fuel, weighed 4¾ pounds, and it flew for distances of 100 yards at a height of 20 feet, coming down only when the steam pressure fell

**We have been favored** by Mr George Westinghouse with the following particulars of his new reduction gear high-speed marine turbine. The rotor complete will weigh about 1½ pounds per horse-power in sizes of from 3,000 to 1,500 horse-power The number of blades of all kinds in a turbine of from 7,500 to 10,000 horse-power will be slightly under 15,000. The total weight of the turbine with rotor will not exceed 7 pounds per horse-power, and the weight of the gearing will be under 2 pounds per horse-power The effect of this reduction of weight is seen in the new naval collier, No. 8, which will carry 300 tons more coal than if she were driven by reciprocating engines. A saving of an additional 800 tons will be realized as the result of the greater economy of the plant in fuel consumption.

## ELECTRICITY.

**The conditions** under which a street lamp should prove its efficiency are very different from those which govern the indoor lamp. This was brought out clearly in a recent address before the New York Section of the Illuminating Engineering Society by Dr Clayton H. Sharp. He pointed out that while in the building it is advantageous to have much of the light of a lamp pass upward and be reflected by the ceiling in the case of a street lamp this would be a great fault for the vertical rays would be lost Only those rays that are cast directly downward and horizontally up and down the street can be utilized For this reason he has devised a reflector consisting of a pair of parabolic mirrors arranged to throw the rays in the direction of the street so that practically all of the light will be used to best advantage Thus, in place of having the street lighted in spots, as is now the case, a more continuous illumination is provided

**The block** signal systems of steam railroads have hitherto been operated with direct current from storage batteries. This has always been an expense owing to the inconvenience and difficulty of maintaining the storage batteries In recent times trolley roads have been using an alternating current signal system which has been found to work very satisfactorily, and the announcement has just been made that the Pennsylvania Railroad is about to install an alternating current block signal system on the line between Dixon, Ohio, and the Grand Rapids and Indiana Railway This is probably the first instance of the use of alternating currents for steam railroad signaling purposes and if found satisfactory should do much toward extending the use of block signals on lines where the direct-current system is impracticable

**In an article** appearing in a recent number of the Electric Railway Journal some very interesting conclusions were arrived at concerning the question of the cost of a street-car ride The nickel surrendered for say, a three-mile ride in a street car is the very cheapest investment a man can make for covering this distance Certainly any other method of transportation would be far more expensive and even the man who walks to his work, if he is earning 15 cents per hour would consume at least 10 cents worth of time instead of the 5 cents spent on the street car In addition to this, the nickel surrendered to the street-car company is an insurance to him against accident while if he rides in an automobile or even if he walks to his work, he would be obliged to pay all damages in case of accident Furthermore the time spent on the street car can be employed in reading business documents or doing other such work

**In view** of the recent agitation in favor of using electric headlights on locomotives, the experiments along this line by Prof Benjamin, of Purdue University, are most interesting Prof Benjamin has found much to be said against the electric headlight Not only does the strong beam of light blind engineers on locomotives coming from the opposite direction but it also has a peculiar effect of producing false signals In one of his experiments the light of a green signal was extinguished, but when the beam from the electric headlight fell upon the green roundel, it was powerful enough to reflect a green light which appeared to the engineer to be a caution signal This effect persisted until the engine was within four hundred feet of the signal On the other hand in favor of the electric headlight it has been pointed out that obstructions on the track are readily seen far enough off to permit of stopping the train before they are encountered Furthermore, on a single-track line, the presence of a train may be detected at a long distance off, and head-on collisions may thus be prevented

**Considerable** attention has been directed of late in the injurious effect of certain rays of electric lamps upon the eye A very interesting communication upon this subject was recently presented by Dr Stockhausen before the Illuminating Engineering Society of London, and he pointed out that an excess of radiant energy, no matter what its wave length is injurious. Hitherto it has been supposed that the red and infra-red rays on account of their heat value, are very injurious to the retina, but Dr Stockhausen does not believe that under ordinary conditions the effect of these rays is very disastrous Certainly in sunlight, these rays may be found in large quantity The best rays for the human eye are the yellow-green rays. The rays from blue to deep violet do not appear to produce serious effects, and even the rays in the ultra violet section of the spectrum do not do very much damage The really injurious rays appear to be those which belong in the extreme ultra violet section. These rays are not found in ordinary sunlight, but appear in the light produced by quartz-inclosed mercury vapor lamps As ordinary glass is opaque to these rays, it is a simple matter to avoid them.

## SCIENCE.

**A telegram** has been received at Harvard College Observatory from Prof. H H Campbell director of the Lick Observatory, stating that "Frank McClean cables from Hobart, Tasmania, steady rain, eclipse invisible"

**A new inflammable** celluloid has been patented by Prof A Gautier The chief feature of the process is the employment of an ether silicate instead of pure ether, which is ordinarily used with alcohol as the solvent in the agglutination of nitrocellulose fibers by means of camphor

**The University** of Paris and the Pasteur Institute have been authorized to conduct jointly a laboratory of radio-activity located in Paris. This new laboratory will be divided into two sections, one of which is reserved for scientific researches under the direction of Madame Curie while the other will be devoted to medical applications of radio-activity and is placed under the direction of the Pasteur Institute

**What does** "gold filled" mean? Probably most people who buy gold filled watches fancy that they are mysteriously impregnated with gold As a matter of fact, the term is misleading Gold filling consists in taking two sheets of gold between which is placed a section of solder-coated base metal This metallic sandwich is heated and pressed so that the three parts are welded together with the gold outside

**Dr E E Barnard** of Yerkes Observatory informs us that despite the haze and clouds of the early morning of May 7th, 1910 he obtained fair photographs of Halley's comet A tail about 20 deg long appeared on the photographs To the naked eye it was only 17 deg or 18 deg long The head was of the second magnitude On one picture the tail showed separately in three strands, some five or six degrees from the head The comet was a beautiful object on the mornings of May 4th and 5th

**In a recent** bulletin issued by his observatory Mr Percival Lowell describes his newly-discovered Martian canals These new canals are two in number and were discovered on September 30th 1909, to the east of the Syrtis Major where no canals had ever previously been seen They were most conspicuous Not a trace of them could be found in the record drawings of August July, June or May when this part of the planet was depicted nor could any trace of them be found in the records of previous years Mr Lowell admits the possibility that the phenomenon might be one that could have been seen before but was not yet the possibility of error seems excluded by the size of the canals in question He regards the evidence as strong that the canals are not simply new to us, but new to Mars Measurement of their dimensions shows each of them to be a thousand miles long and some twenty miles wide The Canyon of the Colorado would be a secondary affair in comparison

**Light** is of very great importance to algæ growing on the sea bottom and in their struggle to obtain light the plants assemble in structures of several stories The algæ of the genus *Laminaria* adhere to the rocks by means of disks The wounds made in the plants by the attacks of animals become covered with a protective secretion in which the countless spores which the sea water contains become entangled and grow This layer of epiphytes is covered in a similar manner by a second layer of plants or of sessile animals the shells of which are again covered with algæ In addition to these variegated structures in which saprophytes and parasites have their place fragments of algæ which have been torn by winds currents and animals take root upon other algæ and form structures of several layers For example the delicate *Ectocarpus* grows on *Laminaria* and is soon covered by the broad root disks of *Rhodolymenia* which are sufficiently transparent to transmit to the *Ectocarpus* sufficient light for its development

**The mineral waters** of Vichy Clermont Ferrand, Mont Doré and Spa contain fluorescent substances in very minute quantities The quantity of fluorescent matter often increases with the temperature of the water and diminishes as the amount of solid residue increases At Spa the amount of fluorescent matter has been diminished by improvement in piping The largest proportion is found in waters containing tarry constituents These results are of practical interest in connection with the piping of mineral springs Nearly all natural waters whether potable or contaminated contain organic substances which are already fluorescent and others which become fluorescent when the water is heated to 266 deg F for half an hour The development of fluorescence is promoted by the addition of five per cent of ammonia All such waters exhibit increased fluorescence when they are heated but this change is not produced by heating the water of a properly piped mineral spring because this water has already been exposed to a temperature of at least 266 deg F in the earth, and a second heating does not affect the fluorescence

### COMET NOTES.

The Lowell Observatory has issued a bulletin entitled Preliminary Notes on Photographic and Spectrographic Observations of Halley's Comet The observations consist principally of direct photographs of the comet and photographs of its spectrum as seen at Flagstaff Halley's comet before April 18th had shown no very striking changes, except in the divergence or separation of the lateral streamers Negatives obtained on April 25th and 27th show marked changes in the form of the tail On the 25th the tail, at a short distance from the head divided into three narrow streamers a central ray and two symmetrical side branches On photographs made on the following morning the tail was again quite narrow and straight On the 27th it was again branched The most remarkable changes noticed at Flagstaff in the comet's tail were observed on photographs made on April 10th and May 1st On April 30th the tail had completely changed in form The more or less bilateral symmetry had entirely disappeared The plates of May 1st show for a distance of about 70 deg a tail well defined with a gentle curvature, but beyond this point faint and diffuse The outer parts of the tail on the last two plates have the appearance of having been acted upon and shattered by some rather sudden and disturbing disintegrating force The comet's nearest approach to Venus occurred about this time The question naturally arises, could the planet have been the disturbing influence? Comparisons of the disappearance of the comet's tail for some days before and after this event may tell us something

The great square of Pegasus acted as a splendid 'finder' both for the comet of 1910 A and for Halley's comet This mutual association of the two comets with Pegasus affords a good example of one of the chief difficulties experienced by those astronomers who have endeavored to trace Halley's comet amid the mass of brief and very general records of comets in ancient chronicles

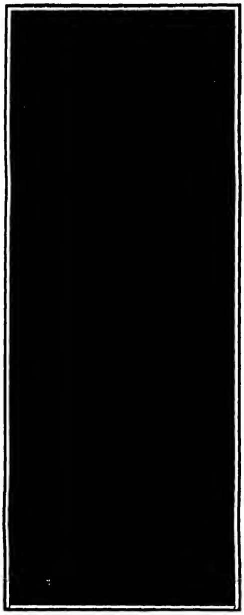
It is unfortunate that the chance of capturing a sample of the tail of Halley's comet was not seized The passage of the earth through a comet's tail is so rare an occurrence that no opportunity should be missed In the April number of the Bulletin de la Société Astronomique de France, C E Guillaume suggested the liquefaction of a large quantity of air which could afterward be treated by fractional distillation, and possibly some cometary matter recognized He pointed out that very minute quantities of the rare gases, such as krypton and argon, are thus secured from immense volumes of air and that it is now possible to liquefy 1 000 cubic meters of air per hour It is just possible that by this means a chemical study of the comet might become a by product of an industrial operation

An investigation of Encke's comet by Dr Backlund shows that the acceleration of the mean motion of that body between 1895 1901 and 1904 was not constant Dr Backlund suggests that the resistance which would explain the phenomenon is a meteoric swarm in the neighborhood of perihelion, and that the decrease of the acceleration must be attributed rather to the diminution of the density of the resisting medium than to changes in the comet itself Dr Backlund also discusses the comet's fluctuations in brightness, but offers no explanation

The passage of the earth through the tail of Halley's comet has led Flammarion to suggest that if there is any palpable material at so great a distance from the head it might be possible to measure the minute rise of temperature produced by the earth as it rushed through the tail at the rate of 48 miles a second

Although comet A 1910 has sped away its peculiarities are still the subject of astronomical comment Thus Dr Wolf comments upon a conical mass of material extending from the base of the coma toward the sun, quite different from anything seen in previous comets, and having the appearance of a miniature zodiacal light.

It was to be expected that the apparition of Halley's comet would not remain without its effect upon the more ignorant peoples of the world, even though this



PHOTOGRAPH OF HALLEY'S COMET TAKEN BY DR. E. E. BARNARD ON MAY 5, 1910

is the twentieth century, and the days of superstition are supposed to have passed Reports from China state that the comet was used as an omen to inflame rioters in disaffected districts. To be sure, the authorities tried to counteract these attempts by exhibiting pictures of the comet with an account of its previous appearances without ill effects, in order to reassure the natives. This Chinese situation finds its counterpart in Europe. The suicide of a Hungarian farmer "on account of Halley's comet," as the newspapers have it, is followed by a report from Odessa that in Southern Russia there is a veritable popular terror which is being exploited by unscrupulous persons for the purpose of obtaining money for special prayers, etc.

Observations of Halley's comet made in Harvard College Observatory on the morning of May 6th lead to the following results The brightness of the nucleus of the comet was measured by Prof Wendell with the 15-inch equatorial, with the resulting magnitude 7 06 The nucleus was, therefore, distinctly fainter than on April 27th, when its magnitude was 6 01. The total light of the comet was greater, being estimated by Mr Campbell as magnitude 2.2 Three photographs were obtained by Mr King which showed a well-defined nucleus. A long tail was shown, which was bifurcated

### THE ACCIDENT TO THE "ZEPPELIN"

The recent destruction of the "Zeppelin" airship again drives home the inherent defects of the rigid type of airship While journeying from Homburg to Cologne, it was necessary to anchor the airship in an open field. On April 25th, at 1 P M, after the vessel had received a new charge of gas, it was torn from its anchor by a storm, and driven away in a northwesterly direction The airship came down at Webersburg in the vicinity of Weilburg on the River Lahn, and was totally destroyed Two companies of soldiers were unable to hold the vessel against the terrible storm In order to prevent a catastrophe, it was necessary to order the soldiers to release the airship, which immediately rose to a height of 700 feet, and was driven away in the direction of Weilburg At 20 minutes past one the airship was sighted from Weilburg Suddenly, probably caused by a downward gust, the vessel was forced down into the Lahn valley In the Lahn valley, where the storm raged violently, the wind blew the vessel broadside and pressed it down to the earth The nose dipped almost into the Lahn, which winds through the valley Then the bow of the "Zeppelin" was caught in the telegraph wires which run along the railway. The metal frame was twisted Trees were bent and telegraph poles were torn down, and with a frightful noise the wind buried the enormous gas bag against the side of a hill and forced it into the trees. Another gust of wind then threw the lower portion of the airship across the hill Aluminium parts, yards of balloon cloth, and steel rods lay in a tangled mass

The catastrophe of Weilburg is the fourth sustained by dirigible airships The first was that of the French dirigible "La Patrie," which during a trial at Verdun on the 29th of November, 1907, had to land in the vicinity of Suesnes The next morning, the wind changed to a howling hurricane. The soldiers who were in charge of the airship were compelled to release the ropes in order not to be carried away In a few minutes the "La Patrie" had vanished, and was never seen again

The next great catastrophe destroyed the "Zeppelin IV.," while Count Zeppelin was on his famous 24 hour record trip of the 4th and 5th of August, 1908 On the return journey about ten kilometers from Stuttgart, Count Zeppelin was compelled to alight at Echterdingen to make repairs. Even before it was possible to cure the defects in the motor, which had caused him to come down, the airship was destroyed To this day the actual cause has not been discovered. The "Zeppelin" caught fire and was burned up in a few minutes.

The next catastrophe affected the French dirigible "Republique." The destruction of the "La Patrie" and the

THE WRECK OF THE ZEPPELIN AIR SHIP AT WEBERSBURG.

# THE THORNE-BAKER TELE-PHOTOGRAPHIC APPARATUS

## AN INSTRUMENT FOR TRANSMITTING PICTURES WITH AND WITHOUT WIRES.

On the evening of May 11th, Mr T Thorne-Baker delivered a lecture before the New York Electrical Society, in which he explained a new tele-photographic apparatus, of his invention The apparatus is to be experimentally tried out in transmitting newspaper pictures between New York and Boston It has been used by the Daily Mirror of London, between Paris and London, and Manchester and London since July, 1909 With some modification, it can be adapted to the wireless transmission of pictures.

Mr Thorne-Baker's apparatus employs no selenium cells and prints the records electro-chemically A print is made from a photographic negative in sensitized fish glue on lead foil The print is made in the usual way, and the parts not acted upon by light are washed away, as in the gelatine process of photography This impression is wrapped around a drum somewhat similar to the drum of an Edison phonograph The receiver consists of a similar revolving metal drum, over which a platinum stylus traces a helical line on a paper impregnated with some colorless electrolyte, the nature of which is not revealed Whenever the transmitter of the stylus touches a clear part of the metal foil, current flows to the receiver, and a black or brown dot or mark appears on the chemical paper The accompanying diagram illustrates the general arrangement of the apparatus

The lead foil picture is broken up into thin and thick lines with spaces intervening The stylus touches the lead base or the fish glue lines, and the time of contact depends upon the width of the line Hence the width of the lines determines the periods of the line currents.

The apparatus is used over a telephone line, the circuit being closed by the two styles $S_1$ and $S_2$ with two batteries $B_1$ and $B_2$, and the split resistance $W_1$, $W_2$ of 1,000 ohms, in shunt. The variable condenser $K$ is shunted across the variable contacts of the resistances, and the currents used to sweep out the residuary charges are regulated with the aid of the resistances $W_1$ and $W_2$. These line currents flow through the chemical paper on the drum, but the pole of battery $B_1$ connected with the style $S_2$ is of opposite sign to that of the line unit connected with it When the leakage on the line is great and evenly distributed, less reverse current is required from the balancer (a device employed to wipe out residuary currents from the line in the way frequently made use of in duplex telegraphy) By increasing the voltage of the reverse batteries $B_1$ and $B_2$, considerably greater contrast can be obtained in the pictures. The finer the half tone screen employed in splitting the half tone up into lines, the higher must be the voltage

In all tele-photograph apparatus the problem of synchronism is one that has always bothered the inventor The best arrangement is that of Korn whose system has been adopted by most recent designers, as well as by Mr Baker The motors, driven through storage batteries at about 3 000 revolutions per minute, are geared down for the drums to 30 revolutions. The speed of each motor is regulated by resistance in series to the field, and the speeds are observed with the aid of vibrating reed frequency meters. A set of tuned steel tongues is fixed in front of a magnet which is fed with alternating currents from slip rings on the motor Each tongue has a different period of vibration, and when the alternations in magnetization correspond with the period of one tongue, that tongue will vibrate The receiving drum is driven somewhat more quickly than the transmitting drum, and, therefore, completes its revolution somewhat before the transmitter It is then stopped by a steel check. When the transmitting drum has completed its turn, a fleeting contact comes into play; a reverse current is sent to the receiver, which flows into a relay actuating the electro-magnet by which the check is removed. Thus, whatever lagging may be is limited to one drum, and the drums are always re-started in unison

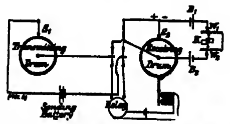

Fig. 1.—General arrangement of the apparatus

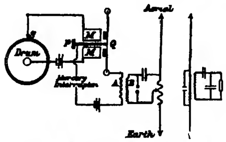

Fig. 2.—Apparatus for transmitting pictures wirelessly

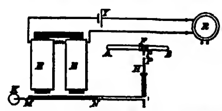

Fig. 3 -Relay employed in the wireless apparatus.

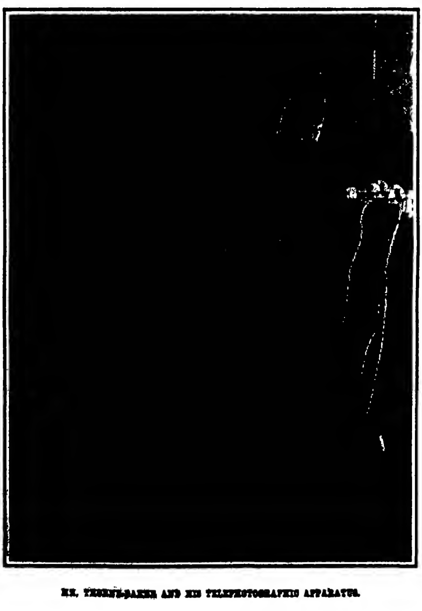
One advantage of Mr Baker's system is to be found in the fact that the entire operation of transmitting and receiving occurs in full view It is not necessary to develop a picture before discovering whether anything is wrong with the apparatus. Furthermore, the transmitting cylinder can be used as a receiving cylinder, if necessary

The ordinary two-station instruments fit into two boxes of moderate size A portable apparatus, however, has been devised by Mr Baker, which he claims can be carried from place to place by an operator, so that pictures can be prepared in the field and telegraphed on Thus plans, positions of troops and of ships can easily be transmitted

Perhaps that feature of Mr Baker's researches which will interest the readers of this journal most is the adaptation of his apparatus to the transmission of pictures by wireless telegraphy The principles may thus be explained Conceive a small incandescent lamp, coupled with the local side of a relay and battery the relay being actuated by means of a coherer When a Morse key, closing the primary of an induction coil, is depressed the lamp glows until the coherer is tapped The taps can be controlled by the lines in a photograph or sketch and the light of the lamp can be concentrated on a revolving photographic film Mr Baker applies the principle in the manner shown in Fig 2 A line picture is attached to the drum of the transmitter, and the intermittent current ordinarily passed into the telephone line flows into the electro-magnet end The magnet $M$ attracts the diaphragm $Q$ and brings the platinum contacts $P\ Q$ together When they are in contact the primary of the transformer is closed, and the spark gap of the secondary, inductively coupled with the aerial and the earth, sends out oscillations Hence the length of the signals and their distance apart are regulated by the lines of which the photograph or drawing to be transmitted is composed

When working with currents of 110 volts, arcing must be prevented This is done with the aid of a mercury interrupter The receiving apparatus is simple and for a short distance involves the use of a coherer cymoscope of peculiar character Whenever the oscillation passes the antenna the coherer becomes conductive and a relay is actuated which starts a vibrating hammer In order that the hammer may strike only once for each signal the arrangement shown in Fig. 3 is employed The relay $R$ actuates the electro-magnet $E\ E$ which attracts the armature $M\ V$ This motion brings the resilient hammer $H$ provided with the platinum contact $P$ against the contact pin fixed to the collar $F$ of the coherer $A\ B$ Thus the local circuit is closed, and a black mark appears on the chemical paper Successive marks can be obtained at intervals of 0 017 second Up to the present this device has been successfully used only for line drawings The apparatus however might be used for the transmission of sketches and plans Mr Baker suggests that military plans could be done in shellac ink on a slip of metallic foil placed upon a portable machine coupled to a military wireless set, and communications could thus be exchanged What is more such a communication cannot be tapped Even if the enemy were in possession of an exactly similar instrument of the same dimensions and screw thread the picture received will be quite confused if the rate of running is altered by five or ten per cent, according to pre arranged signals

A special form of Einthoven galvanometer is employed by Mr Baker for working the relay which galvanometer has a very intense magnetic field Instead of the usual silver wire a silver quartz fiber one twelve hundredth of an inch in thickness is employed This galvanometer is combined with the valve receiver for detecting wireless oscillations recently invented by Prof Fleming When the rectified currents which in ordinary radio-telegraphy cause the telephone to sound, are sent through the silver quartz fiber the string is shifted The shadow of the string lies over a fine slit, which is thus opened by the oscillations In order to be able to use



MR. THORNE-BAKER AND HIS TELEPHOTOGRAPHIC APPARATUS.

a wider slit Mr Sanger Shepherd has fitted the apparatus with a fine shutter, and in that case the receiver can be modified The beam of light is then directed through the tunneled poles of the electro-magnet, and a pair of narrow compensated selenium cells is placed behind the slit, a positive lens being interposed Any dot received shifts the fiber laterally, light falls on the selenium cells, and their reduced resistance allows a battery to actuate a relay which throws the telephotograph receiver into circuit

### HOW THE "FLORIDA" WAS LAUNCHED

The launching of the 'Florida,' which took place strictly according to schedule, at the Brooklyn navy yard on the morning of May 12th, was an unusually brilliant function In its technical aspects the launch was particularly successful, and we offer our congratulations to the naval constructors who were directly responsible The ship is now tied up at the navy yard dock, where she will receive her side armor, which is already assembled at the yard, and her turrets which are also about ready for placing

A most interesting feature of the day was a dinner in celebration of the event, given by the employees of the yard who built the ship This event at which some 1 200 were present, included among the speakers Vice President Sherman, Governor Gilchrist of Florida Assistant Secretary Winthrop of the navy, Admiral Leutze, the commandant of the navy yard, Naval Constructor Baxter, and others. Capt Baxter referred to the strong personal interest taken by the whole force of men who worked upon the Florida" in the success of the ship To the Editor, who was present as a guest, the genuine enthusiasm raised among the men whenever any reference was made to the ship, the yard, and its officers seemed to be a strong indorsement of the policy of having at all times a battleship under construction at the New York yard

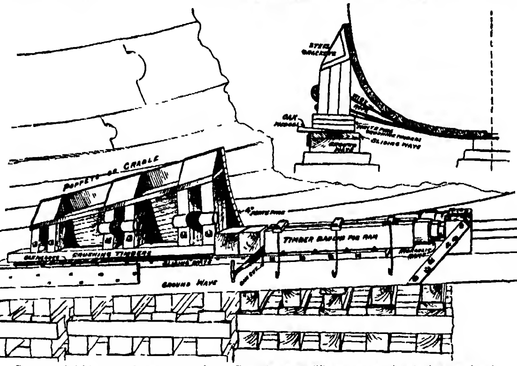
In response to several inquiries as to just how a battleship is launched, we have prepared the accompanying sketches, showing a portion of the launching ways near the bow The permanent or "ground' ways consist of rows of piling driven to a solid bearing upon which are spiked heavy, square timbers, or "caps,' running transversely Upon these are laid series of heavy, longitudinal square timbers in three parallel lines, one immediately beneath the keel, and one on each side of the ship between the keel and the bilges During construction the weight is carried upon the keel blocks and upon hundreds of shoring timbers. When the ship is ready for launching and a few minutes before the actual launch the weight of the ship is transferred from the central keel blocks and the shoring timbers to the two parallel lines of launching ways Each permanent way, built up of heavy, square timbers, presents a sliding surface four feet wide extending the whole length of the ship and down a considerable distance into the water The permanent ways are fastened firmly down to the cross caps and piling below The launching ways which are also four feet in width, are attached to the hull of the ship, and move with it down into the water Between the under surface of the launching ways and the upper surface of the permanent ways is a thick coating of grease, oil, and other lubricating substances. The launching ways have to be molded to the form of the ship for which they form a cradle, and our drawing shows part of the cradle near the bow, which is known as the forward "poppets." The poppets consist of six sets of 14 inch by 14 inch timbers in groups of half a dozen At their upper ends these timbers bed against heavy angle iron brackets, and at their lower ends they rest upon what are known as the "crushing timbers" long lines of parallel timbers four feet wide the bottom one of which forms the sliding surface of the launching ways The above-mentioned angle irons are riveted to steel straps from a half inch to three-quarters of an inch thick and 42 inches wide which extend down below the keel and up to similar brackets on the other side of the ship The space between the straps and the hull is filled in with four inch white pine timbers, which form the bed in which the bow of the vessel rests. To assist in tying the whole cradle together, heavy wire ropes pass beneath the bow and are carried around heavy oak thimbles, placed on the outside of the poppets. Further support is given by 1¾ inch tie rods, which are drawn up snugly by nuts on the outside of the poppets.

The crushing timbers are provided throughout their entire length with a series of oak wedges interposed between them and the launching ways below About half an hour before the launch, hundreds of workmen range themselves up and down the ways, and by means of heavy sledges drive these wedges home, forcing the launching cradle into closer contact with the ship, and eventually lifting it sufficiently to clear it from the keel blocks, thus transferring the load entirely to the launching ways.

This brings us to the consideration of the interesting method by which the ship is held in place, and prevented from starting off down its well-greased "toboggan" until the exact moment when the christening is performed and the order is given to let go The locking and starting gear are as follows

The hardwood launching ways are extended forward and strongly bolted down to the ground or permanent ways. After the wedges have been driven home, and the ship is resting on the inclined and well-greased surfaces it is prevented from moving solely by these bolted connections At the critical moment, at the word of command, carpenters armed with cross-cut saws commence to saw through these timbers, and as the cut is made, a point is soon reached where the tensional strength of the remaining timber fails to hold the vessel. It parts with a loud report, and almost invariably the ship starts, slowly at first, and then more rapidly, for the water

Occasionally a vessel will stick and must be given a start. For this purpose, four heavy ramming timbers are laid in position abutting against the end of the launching ways, with hydraulic jacks interposed between them, and heavy timber abutments. Should the ship "hang," a brief operation of the jacks is generally sufficient to start her



The upper end of sliding ways is bolted to the ground ways. To free the ship, the sliding ways are sawn through, when a push from the hydraulic rams (if necessary) sets her in motion

LAUNCHING WAYS AND CRADLE OF "FLORIDA" NEAR THE BOW

### Reducing the Number of Appeals in the Patent Office.

Mr Frank D Currier of New Hampshire introduced on January 21st, 1910, a bill the principal purpose of which is to expedite the granting of patents in the Patent Office, and to eliminate one appeal in the office In his last annual report the Commissioner of Patents recommended such legislation and advocated a measure which would combine the Commissioner, the First Assistant Commissioner, the Assistant Commissioner, and the Examiners-in-Chief into a single appellate tribunal, any three of whom shall constitute a quorum, to which all appeals shall lie, whether from the Primary Examiner or from the Examiner in Interferences, and from which appeals would lie to the Court of Appeals of the District of Columbia.

Under the present patent law in *ex parte* cases an appeal lies from the Primary Examiner to the Board of Examiners-in-Chief, then to the Commissioner (the First Assistant Commissioner or the Assistant Commissioner), and from his decision to the Court of Appeals of the District of Columbia. In interference cases, the course of appeal from the decision of the Examiner of Interferences is the same. This course of appeals undoubtedly imposes an unnecessary amount of delay and expense, throws upon an over-burdened Commissioner the impossible task of giving to each case the amount of personal attention proper to its disposal, as demanded by law Lastly, the Board of Examiners-in-Chief, as at present constituted, consists of three members, and no provision is made under the present law to supply a temporary vacancy caused by sickness, or other cause, with the result that the absence of one member sometimes results in an unevenly divided Board, and in the consequent necessity for a rehearing The absence of two members causes an entire suspension of business.

The enactment of Mr Currier's bill into a law would provide an appellate Board, any three members of which would constitute a quorum, the prosecution of all applications on appeal would be expedited, and the elimination of one appeal would mean the saving to the inventors of one appeal fee, attorneys' fees and incidental expenses Lastly, one appeal in the Patent Office instead of two would give greater stability to the decisions of the office tribunals, and would also obviate any want of agreement that has at times existed in the past between the decisions of the Commissioner of Patents and the Assistant Commissioners.

The bill is in reality Commissioner Moore's bill, for it was submitted by him to the Secretary of the Interior, who made a careful study of it and transmitted it for the consideration of Congress. The patent profession, as a whole, is in favor of the measure

The value of the measure will be appreciated when we consider the manner in which the Patent Office does its work Each of the forty-two examining divisions deals with a special class of inventions. The Board of Examiners-in-Chief, consisting of three men at present, must deal with inventions from all of these forty-two divisions, covering the entire range of mechanical arts, chemistry, electricity, and the like The members of the Board cannot be experts in all of these widely diverging fields of activity They must inform themselves upon all these classes of inventions as they come before them They are supposed to have a special knowledge of all the legal points which are likely to be involved in the appeals on mechanical questions. They must study up and inform themselves so as to be able to explain the technical point at issue Obviously, in order that these men may keep up with the times, it is necessary for them to study and read much At present there are hearings every afternoon beginning at one o'clock There are on the docket seven or eight *ex parte* cases involving the patentability of an invention, or one to two interference cases involving the consideration of testimony taken on both sides, the application of the law, and frequently, the right of the applicant to make the claims. Hence, only the forenoon is left for study and what reading is necessary and the preparation of decisions. It is small wonder that the Examiners-in-Chief find it almost impossible to keep up with their work. Driven to it, they can make some sort of a decision, but to do so properly the invention must be studied thoroughly, and in interference cases the testimony must all be read, even though it may involve thousands of pages. With only three men on the Board, the time has come when it is necessary to do something in the way of relief, so that prompt and correct decisions may be handed down. Just now the Board is several months behind its work. The result is that to get an appeal through the Board of Examiners probably requires three to four months' time. The bill in question saves so much time in getting a case through the Patent Office It practically provides six men to do the work that three are now trying to do, without any additional cost.

At the present time, the same work is done over twice in the Patent Office for no very good reason. The theory of the present course of appeals is that under the decision of the present Board of Examiners-in-Chief, there will be an appeal to the Commissioner in person. It is impossible for the Commissioner of Patents in person to give due consideration to all

these things which are appealed to him. He has to have the help of his Assistant Commissioner, and he also has to have the help of law clerks. The situation is, therefore, this: Instead of getting the decision of the Board of Examiners-in-Chief, the only chance the Board has of getting together and forming an opinion on a case is after hearing the arguments which are made by the attorneys. The Board then tries to come to some conclusion at that time. If it does not, then the work is to be divided among the members of the Board, and each one has to prepare his share of the cases, and then explain his decision after it is rendered to the other members of the Board, whereupon they decide whether they will concur or dissent. Obviously, the decision does not exactly represent the views of all the members of the Board. Sometimes they have so much work to do that they have to pass it over and sign it any way.

For these reasons, it would seem that the Currier bill is worth enacting into a law.

## A PHENOMENAL OIL GUSHER.

BY CHARLES CARROLL WRIGHT.

The largest oil gusher in the history of California, and perhaps the most profitable in the world's history, is the Lakeview in the Maricopa oil field, forty miles southeast of Bakersfield, Cal. The gusher started to spout on Tuesday morning, March 15th, and, save for a period of eight hours in which it "sanded up" on March 21st, when it burst forth of its own accord like a volcano of oil, the well flowed continuously up to March 31st, averaging a flow of 48,000 barrels of oil of 18 gravity Beaumé each 24 hours, as measured in the run-off from the sump hole through a ditch in which the oil runs to a rapidly built pipe-line. Since that date the flow has continued at the rate of from 42,000 to 45,000 gallons, and up to May 3rd it had delivered about 2,000,000 barrels of oil.

The marvel of the gusher has been its sustained productivity. During the two weeks following March 21st, 1910, more than one-half million barrels of high grade crude petroleum had been collected from the well. The stream rises intermittently from 170 to 240 feet above the top of the derrick, which, before the crown or top was carried away by the stream of oil, was 84 feet in height. The oil sands were struck at 2,300 feet, at which point a tremendous gas pressure was encountered and the drillers were suddenly amazed at seeing small rocks hurled hundreds of feet in the air through the eight inch casing. After the oil sands were struck, the well rapidly "drilled itself" to a greater depth. The well promises to keep spouting for many months to come.

The well can be heard roaring for more than a mile. Spray from the gusher has been carried a distance of two and a half miles, and hundreds of automobiles have carried sightseers from Bakersfield to witness the unique sight. The sage brush for a distance of half a mile around the well is coated with oil, and several jack rabbits killed by the flow were brought by small boys into Maricopa. All efforts to "cap" the gusher have proved unavailing, the force of the oil flow carried away the crown or top of the derrick and fifteen feet of its uppermost structure, and the tremendous flow created a huge lake of oil extending for hundreds of feet on every side of the derrick.

From a money viewpoint the gusher is said to be the most valuable in the world's history, far exceeding the famous Texas gusher in the Beaumont field, which caught fire and subsequently ran into salt water, for the owners of the Lakeview had netted by March 21st over $200,000 from the oil, which is now being piped to tidewater from Maricopa in the San Joaquin valley to Port Harford on the Pacific coast, a distance of 150 miles.

To control the oil from the gusher was in itself no slight achievement. Shortly after the great stream amazed the drillers, three pumps with a combined capacity of 25,000 barrels daily, were started working at top speed, pumping oil out of the sump-hole, and the oil so recovered was the first oil to enter the huge tanks built by the Independent producers of California.

The big well, which is one of the seven gushers "brought in" in the Coalinga and Midway-Maricopa oil fields of California within the past month, is due to the persistency of a single man. A discouraged board of directors, three days before the gusher was struck, decided to quit drilling. The order was given, but the superintendent conveniently forgot it. He drilled 47 feet more against penalty of dismissal, and the bit entered the oil sands.

To date all efforts to cap the well have proved unavailing, and the oil is now rushing heavenward both on the inside and the outside of the steel casing.

It is an interesting fact that lately the gravity of the oil has risen from 18° Beaumé to 20°. This has been taken to indicate that the oil is now being drawn from a lower stratum or "pool."

# Correspondence.

## WEIGHT DISPOSITION IN AEROPLANES.

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of April 30th Mr. Godfrey assumes that the center of suspension and center of thrust are coincident, center of gravity low, and center of resistance to the lateral motion in vertical rudder high.

In an aeroplane with perfect stability the center of gravity should be low, the center of thrust below the supporting plane yet in the center of resistance to forward motion and the vertical rudder below the center of suspension yet at the center of resistance to lateral motion. In my monoplane the operator by shifting his weight slightly can raise the inner wing in making the turn. MOSES FRANKLIN.

Grand Junction, Colo.

## WEED-CUTTING BOATS.

To the Editor of the SCIENTIFIC AMERICAN:

I have been a constant reader of the SCIENTIFIC AMERICAN for, I think, more than thirty years—back as far I can remember, anyway. In the issue which I received Saturday, I noticed an illustration of a weed-cutting boat and a description sent by your Paris correspondent. While I do not know that there is a specific statement in the article that it is a new scheme certainly one can only gain that inference from the reading.

While I do not remember to have seen a weed-cutting boat exactly similar to that one, they have been in use in this country by many of the ice companies for many years. The Consumers' Company of this city, of which I was vice-president and general manager for a good many years, something like ten years ago built a boat at their own works for this purpose, and while owing to the fact that gasoline engines were not then so universally used as at present steam power was used for its propulsion and for the operation of the cutting knives, yet its purpose was the same and it accomplished the same end and in my judgment was in some respects better than this French device. As I remember it, we merely built a flatboat about ten feet wide and forty feet long. We mounted the wheel at the stern, after the manner of Mississippi River steamboats, instead of at the bow as in the French boat and we placed the cutting knives at the bow. They were about the same type as those used on mowing machines and were operated by the same engine that propelled the boat. We merely used a small upright boiler and a single-cylinder vertical engine for power, transmitting the power to the stern wheel by chains and to the cutting knives by bevel gears and shafting. Right at the front end of the boat convenient to the pilot, was a clutch for throwing the cutting knives in and out of gear. The knives were raised and lowered by a gear controlled by the same person. This boat at times was run by one individual. Of course, it was better to have two—one as engineer and the other as pilot. It was arranged to cut to a depth, I think, of four feet.

I know of several boats of this same character used by various ice companies and I think in one respect they are very much better than the French boat as the cutting knives are in front, and the pilot knows just what he is doing all the time and of course, he can run the boat very much nearer the shore and cut the weeds out in very much shallower water. Then again, the French boat runs over the tops of the rushes, pushing them down possibly so that the weed cutting knives would not cut them at all.

Chicago, Ill. JOHN BENHAM.

## Death of Prof. Angstrom.

The well-known Swedish physicist, Dr. Knut Angstrom, is dead. To the general public his passing will mean little, because his investigations were not of the character that attracted public attention. To the scientist his death means a sad loss for in him physics has been deprived of one of its ablest investigators.

Prof. Angstrom was the second generation of a family distinguished for its scientific researches. His father, Johan, achieved fame by reason of his splendid study of the solar spectrum. His son, Knut, was born in 1857. He studied at the University of Upsala, where he afterward taught. He occupied a professorial chair at the time of his death.

Angstrom's first researches were made in the field of spectroscopy. By means of the spectrobolometer he studied the phenomena of absorption in the infra red spectrum, notably for carbon monoxide, carbon dioxide, water vapor and ozone. These investigations gave rise to an interesting controversy with Arrhenius. Water vapor, carbon dioxide and ozone have a marked influence on the temperature of our globe. In effect, they partially hamper the radiation of the earth into inter-stellar space and thus aid in maintaining the surface of our planet at a temperature compatible with the conditions of life. With these facts as a basis, Arrhenius built up an ingenious theory to account for the glacial period. He supposed that the quantity of carbon dioxide contained in our atmosphere has increased since that period. Angstrom proved that Arrhenius' reasoning was valid only for carbon dioxide of almost infinite tenuity and that the possible variations of the tenuity of carbon dioxide in the air could not possibly have had any influence on the temperature of the earth.

Angstrom's name will be forever linked with the study of solar radiation. An instrument which he invented for the purpose of measuring this radiation and known as the Angstrom pyrheliometer is now widely used in observatories.

## The Current Supplement.

The government dam across the Salt River at Roosevelt, Arizona is nearing completion after about six years of active work. The dam is excellently described and illustrated in the opening article of the current SUPPLEMENT No. 1794 by Edmond G. Kinyon. In an article entitled "New Methods of Polar Explorations" the forthcoming expeditions of Lieut. Wilhelm Filchner and Capt. Scott are described in detail as well as other expeditions. The current problems of most interest to those engaged in the branches of science associated with marine construction are usually brought into high relief at the annual meeting of the Institution of Naval Architects. In the present year this has been particularly the case. A summary of the Institution's proceedings is presented. The inauguration of the Oceanographic Museum at Monaco took place on March 28th in the presence of representatives of the governments of France, Germany, Italy, Spain and Portugal, and a great gathering of men of science of all nations who were invited by the Prince of Monaco. The museum is made the subject of an interesting illustrated article. Dr. E. E. Barnard of Yerkes Observatory has made a special study of the aurora. In the current SUPPLEMENT the results of his observations between 1902 and 1909 are presented. On May 18th, at 9 P. M. eastern standard time, Halley's comet will pass directly between the sun and the earth and its tail will sweep over and envelop the earth. In this connection it is interesting to note that a miracle book of the sixteenth century mentions the passage of a very large comet between the earth and the sun and a phenomenon apparently connected therewith. The circumstances of the passage as given in the work are published. Perhaps the biggest comet of the nineteenth century was that of Donati which appeared in 1858. At the time Charles Dickens was Editor of Household Words, in the pages of which magazine there appeared an interesting article on the appearance of the comet—interesting because of its attempt to present the phenomenon in a popular way and also curious in the light of our more advanced cometary knowledge. "Visible Molecules, Corpuscles, and Ions" is the title of an article in which the modern theory of matter is discussed.

## A Stabilizer for Aeroplanes.

Regnard has designed an automatic device for steadying the flight of an aeroplane in which use is made of the invariability of the axis of rotation of a gyroscope. For stabilizing an aeroplane however it is not necessary to have a gyrostat of great mass, acting directly upon the axis of the aeroplane. A small gyroscope, weighing only a few pounds, suffices to establish electric contacts in the frame which contains it. By means of these contacts currents are sent through motors which operate the steering organs of the aeroplane. Two motors are required for this purpose but they may be very small and light because they act upon the rudders by means of levers. Regnard has not yet had an opportunity to apply his invention to a real aeroplane but he has submitted to the French Academy of Sciences a model of an aeroplane about three feet long resting on a box which contains a gyrostatic stabilizer. When the system is inclined in any way the steering organ, whose function it is to restore the axis to its original position, is at once automatically set into motion.

## What One Firm Pays for Patents.

A recent report of the General Electric Company covering the period of the eleven months ending December 31st, 1909 contains some remarkable figures. During the fiscal year the company paid for patents and patent litigation the sum of $904,207, which sum is not counted as an asset but is charged over to profit and loss. All the company's valuable patents, franchises and good wills stand in the balance sheet at a nominal valuation of one dollar.

Mr. Richard Blees, an inventor who did much to improve machinery of various kinds, died recently at Richmond Hill, Long Island, at the ripe age of 95 years. He patented the Culver switch and the first scaling ladder used by the New York Fire Department. Hydraulic water-pressure systems for sky-scrapers and improvements in sewing machines are also to be credited to him.

# THE MANUFACTURE OF TWINE

BY DAY ALLEN WILLEY

What is generally known as hemp twine, used in such enormous quantities for various purposes, is manufactured from two varieties of fiber known as Manila and Sisal Needless to say the first named comes from the Philippine Islands forming one of the principal products of this possession of the United States while the Sisal is secured principally from Mexico the State of Yucatan contributing the largest supply An idea of the extent of Manila hemp manufactured can be gained when it is stated that each year no less than 125 000 tons are shipped from the city of Manila most of it coming to the United States

The fiber from the Philippines is obtained from a species of the banana family, which attains a height of fifteen or twenty feet The stems of the separate leaves grow in a close cluster forming what appears to be a solid tree trunk, to the height of ten or twelve feet, where they separate and branch out like the limbs of an ordinary tree

Type of spindles used for converting hemp into twine

The natives cut these stalks off near the ground removing the leaves from the top of the stalk, then separating the stems and removing the pulp from the fiber by repeatedly drawing it across the edge of a dull blade pressed on a block of wood This primitive method of cleaning the Manila fiber has not as yet given place to modern machinery The average day s work of a native is eighteen pounds of cleaned fiber

This work of growing and cleaning the fiber is confined to the mountainous districts After the fiber has been dried it is packed in convenient sized bundles and brought down to the coast villages where it is purchased by exporters, who sort the fiber and press it by machinery into bales convenient for shipping These bales are protected by mattings woven or plaited from rushes by the natives, and are secured by rattan bands

The Henequen plant furnishes the Sisal fiber which is brought to this country The plant bears a remarkable resemblance to the well known century plant and is frequently mistaken for the latter on account of its appearance As it forms one of the principal products of Yucatan the Sisal plant is cultivated on large plantations, principally by Indian labor The young plants on these plantations are set out in rows about ten feet apart About the fifth or sixth year the plant is sufficiently matured, so that the under and larger leaves are cut, and the pulp removed by decortication, leaving the fibers to dry in the sun, they are then baled ready for market The plant continues to grow and produces about a dozen mature leaves each year At the end of a period ranging from fifteen to twenty years the plant dies, and is replaced by a young one

The method of gathering the Sisal and shipping it to market is much more systematic than the process employed in the Philippines, for nearly all of the Sisal plantations have tramways extending through the Henequen fields, so that as fast as this curious harvest is gathered it can be loaded directly on cars and drawn by mules to the factory, where it is converted into fiber. This is done by the usual method of decortication The material is fed into the receiving hoppers of the mill by means of an endless conveyer, the leaves being laid upon the surface of the conveyer side by side By means of toothed wheels they are cut lengthwise into shreds. In this state the material is passed through mechanical cleaners which remove all of the pulp. Next the fiber passes out of the decorticator and is carried to yards adjacent to the mill, where it is hung upon lines and dried by exposure to the heat of the sun This process concluded, it is pressed into bales of convenient size, and is then ready for shipment to the United States. As already stated, the preparation of Manila fiber is done almost entirely by hand, and before being exported it is also dried in the sun, the natives using long poles, however, instead of rope or wire as at the Mexican plants

Machines for balling the twine.

The manufacture of both the Manila and Sisal fiber into the twine of commerce is performed by practically the same process The interior of the modern twine factory is somewhat similar in appearance to that of a modern cotton mill, with the exception that some of the machinery utilized in the latter is missing This is due to the fact that less care is required in the preparation of the fiber for spinning, since its appearance usually does not increase the value of the finished product. As is well known, the preparatory machinery in a cotton mill is by far the most elaborate apparatus installed It includes the opening and scutching machine, by which the material is cleaned from dirt and other foreign particles. As the fiber is not a mass of lint like raw cotton, this mechanism is not required, nor is it necessary to form it into bats preparatory to carding In the modern twine mill, however, the fiber is passed through mechanism which is somewhat similar to the carding engine and performs the same duties, disentangling the fiber by means of revolving cylinders provided with cards which are suitable for treating such coarse material When carded the fiber is drawn into a conduit, through which it passes between calender rollers and emerges from the machine in a coarse strand It is then coiled in large heaps either upon movable racks or the floor This is the first process in preparing the hemp—for such it has now become—for spinning, but before being conveyed to this apparatus, it goes through what is called the finishing machine. This combines in part the drawing and slubbing frames of the cotton mill, so that when the material emerges from it, the strand has been considerably reduced in size and is slightly twisted, enabling it to be coiled in cans, from which it is fed to the spinning jennies While the spinning machine is of course designed for treating this fiber especially, it is as automatic in its operation as the modern self-acting mechanism, and no more human labor is required to convert the sliver into finished product than is required in the manufacture of yarn and thread from the ordinary cotton. The twine spinning machine includes drawing rolls for lengthening the sliver, the material as it issues from them being twisted by the action of the spindles mounted upon carriages which adjust themselves to the movement of the drawing rolls.

As fast as the twine is spun it is also wound on a large spool or bobbin the latter being taken to the balling machine as soon as it is filled with the twine. The balling machines are also automatic in their operation, not only winding the ball from the bobbin but discharging the finished ball automatically when it has reached the proper dimensions Those machines are calculated to wind balls weighing five pounds each where the twine is used in connection with binders and other agricultural machinery, the balls being packed into cases holding ten each

At the McCormick plant, which is illustrated in the accompanying engravings, several grades of hemp twine are produced, one of which includes the mixture of Mexican and Manila fiber, as this is found to be very durable To show the difference in the weight of the material it may be said that a pound of such twine contains 600 feet The twine made entirely from Manila is slightly finer and averages 650 feet to the pound, while the Sisal is the coarsest, averaging 500 feet to the pound

Bales of twine ready for shipment

THE MANUFACTURE OF TWINE.

---

**Educating the Farmers by Rail.**

BY H. A. CRAFTS

California sees a way to solve the food problem by educating the farmers.

She believes that the farmer is never too old to learn.

She also believes in teaching the young to be farmers

Accordingly, the State maintains a college of agriculture, a university farm, polytechnic school, United States experiment stations, etc.

Now she proposes to introduce the study of agriculture into the public schools of the State.

A substantial beginning in this line has already been made in the establishment of the study in the high schools, later on it will find a place in the primary and grammar schools.

Then California has its farmers' club, granges, and farmers' unions scattered all over the State, and these organizations exercise a large influence upon the educational thought of the day

Every year some hundred or so farm institutes are held in various parts of the State and reach annually between 20,000 and 25,000 farmers.

California has the best organized horticultural soci-

mission in the world, comprising a central office and State insectary at Sacramento and a quarantine department in San Francisco.

Each county covering a horticultural section also has its own local commission, inspectors, etc., while the fruit growers hold two State conventions annually.

These all wield a strong educational influence and add largely to the sum of farm knowledge in the State.

But the latest and most striking feature of California's campaign of farm propaganda is the so-called "Agricultural and Horticultural Demonstration Train."

This train is the joint work of the California College of Agriculture and the Southern Pacific Company, the one supplying the exhibits and corps of lecturers and demonstrators, and the other a fully equipped railroad train comprising three exhibit cars, a lecture car, a sleeping car and diner, all absolutely free of cost to the State.

Separating the coarse from the fine fiber.

The work of the train is arranged in a series of annual tours, covering all the leading agricultural and horticultural sections of the State.

Each series consists of five separate tours, each tour covering from 500 to 1,000 miles, and from twenty to twenty five stopping places. The work of the train begins in the late fall and ends in the late spring. It does not specialize like the demonstration train of the East but covers all the leading lines of agriculture and horticulture.

Its corps of lecturers contains some of the ablest members of the faculty of the College of Agriculture, and the president of the university, Benjamin Ide Wheeler, frequently joins the train in its course, and lends his aid to the work of general farm enlightenment.

The Southern Pacific Company very candidly admits its own interested motives in the premises, and frankly explains that it discovered a serious falling off in its local tonnage, and when the matter was investigated it was discovered that the shrinkage was found in the item of farm produce.

They consulted their local freight agents as to the underlying causes, and were told that the principal cause was an exhaustion of the soil.

This was hardly believable, and the company consulted the soil experts of the College of Agriculture who denied the theory of exhaustion, but explained that the soil had been depleted by a practice of poor cultural methods.

This led to the organization of the "Agricultural and Horticultural Demonstration Train."

And it only needs a glance at California's industrial statistics to convince one of the truth of this charge of wasteful husbandry.

California thirty years ago was one of the leading wheat-producing States of the Union. In the year 1879 its wheat output amounted to not less than 1,707,500 tons, in 1904 the annual product of wheat had dwindled to 465,028 tons, a shrinkage of more than seventy five per cent.

California was formerly a great exporter of wheat and flour. In the year 1882 she exported not less than 1,128,031 tons of wheat and 919,898 barrels of flour.

In 1904 her exports of wheat had dwindled to 54,381 tons and flour exports to 882,486 barrels. To-day both the export of wheat and flour are nil and the State is compelled to import a million dollars' worth of wheat annually in order to keep her mills running, and her flour up to standard grade.

And all a result of poor farming, as is evidenced by the fall of the average annual yield per acre of wheat from forty to less than fifteen bushels.

Combing out the hemp preparatory to shipment.

It is this era of wasteful farming that California desires to put a stop to, and hence inaugurates her campaign of agricultural education.

The "Agricultural and Horticultural Demonstration Train" is developing unlooked-for efficacy. It was originally intended for the enlightenment of the present generation of farmers, but its influence is being carried beyond that limit, it is being brought to bear upon the rising generations, and the young folks are fully as much in evidence at the lectures and demonstrations as the older ones.

At each stopping place for lectures the local schools of all grades are dismissed and the pupils allowed to attend, a privilege that is evidently appreciated by all.

They crowd the demonstration cars and lecture car, attend open-air lectures, lectures and discussions in neighboring school rooms, public halls, and opera houses, and are found in attendance whether the gathering be in the daytime or in the evening.

The subjects dealt with by the agricultural and horticultural lecturers cover a wide field, including plant culture, plant diseases, and plant pests, viticulture, animal industry, dairying, seeding and soil treatment, etc.

Special stress, however is laid upon the vital importance of restoring the lost fertility of depleted soils and the maintenance in their composition of that vital element known to agricultural sciences as humus, all of which has a direct bearing upon the increase in the production of food-stuffs sufficient to supply the demands of a constantly increasing population.

**Fire Control in the National Forests.**

Probably one of the best things in the line of an agreement has just been signed by the Secretary of Agriculture and several railroads whose lines run alongside of the national forests. Two of the largest and longest roads in the Northwest (the Great Northern and the Northern Pacific) have right of way through some of the richest timber districts in the West and this agreement is of great benefit.

They have in view both the reduction to the lowest point of fire risk from the operation of the railroads and joint action by the Forest Service and the railroads to fight all fires which may start along the lines. Both companies have agreed to clear and keep clear of inflammable material a strip of varying width, as conditions demand, up to 200 feet beyond the right of way, and to provide all locomotives which do not burn oil, with suitable spark arresters and other standard equipment to prevent the dropping of fire. An effort will also be made by the companies to so operate their engines as not to cause fires.

In fighting fires the railroads and the Forest Service will co-operate closely. Notification will be made promptly to the Forest officers of all fires discovered by employees of the railroads. Telephone wires to make this possible will be put up by the Forest Service using the companies' poles where this is possible. Warning whistles will also be sounded by locomotives on occasion.

Winding the material into canisters for spinning.

Forces of fire fighters will be assembled on the outbreak of fires, and will be made up of Forest officers, railroad employees, and such temporary labor as can be gathered by either. The cost of fighting fires which start within 200 feet of the railroads will be borne by the companies and of all others by the Forest Service, unless it is shown in the first case that the railroads were not responsible or in the second case that they were responsible for the outbreak of the fire. It is the intention of the Forest Service to patrol the rights

(Concluded on page 427)

Preparing the hemp for spinning.

# DAMMING THE MISSISSIPPI

BY W. P. GREEN

Excelled only by the monster dam across the historic Nile River, the greatest engineering feat in the history of the Middle West is under way on the Mississippi at Keokuk Iowa the point from which Col Roosevelt started his river journey to the far West several years ago A huge dam is being built across the Mississippi at the foot of the rapids which lie to the north of Keokuk, and the stored energy of the river is to be used in generating over 200 000 electrical horse-power The power will be distributed throughout the Middle West, the first long distance transmission line running to St Louis 170 miles south of Keokuk where forty per cent of the power to be developed is now under contract The bed of the river at this point affords an excellent rock foundation The dam will be built of reinforced concrete, and over 500,000 barrels of cement, and 7,000 tons of steel will be required in the construction of this gigantic work

The dam, including abutments, will be 4 700 feet long, or seven-eighths of a mile The spillway section will be 4,400 feet in length The dam will rise 37 feet above the river bed, and the base has a width of 43 feet. On top of the spillway will be placed 116 steel flood gates, 30 feet wide and 11 feet high, supported by concrete piers. The piers are to be built integral with the dam, being carried down to bed-rock on the upstream side They will support an arched bridge, from which the gates will be operated by electric hoists. Through the manipulation of these gates the water above the dam will be maintained at a constant level at all seasons

Four fifths of the dam, tha 4,400-foot section, will extend in a straight line across the river, breasting the current of the broad river The balance of tha dam will be built approximately parallel to the shores and at right angles to the main dam This portion, 1 100 feet long 123 feet wide and 133 feet high, will be occupied by the power house The substructure, built of massive concrete, will contain the water passages and waterwheel chambers Upon this will be the superstructure containing the electric generators, transformers and switchboards There will be thirty power generating units each consisting of a vertical steel shaft, carrying on the lower part two turbines, or water wheels On the upper part, on the floor of the power house, will be the revolving parts of the generators.

To keep floating ice and logs from entering the power house, an ice fender will be built upstream from the upper end of tha power house, curving in toward the shore This will be 2,800 feet long and built of concrete masonry.

The construction of the dam will entirely destroy tha government canal, built to carry shipping around the rapids. This canal now consists of three locks. In its place a single large lock will be built. There will thus be substituted for the canal a lake of deep water over a mile wide at the dam, and 40 miles long. The government has given permission to build the dam. Landowners on both sides of the river will be given a fair price for all land overflowed as the result of the creation of the reservoir

Tha construction of this gigantic river project is under tha direction of Hugh L. Cooper of New York city The work of excavation is well under way on the Illinois side of the river, the project will be pushed as fast as the material is delivered at the site

This huge structure, over a mile in length is being built across the Mississippi at Keokuk, Iowa. The dam, which is broadly similar to the Assouan dam across the River Nile, is provided with 110 flood gates to control the height of the floods. A lake 40 miles long will be formed and ultimately 200,000 electric horse-power will be generated in the power house shown at the left of the dam,

THE HUGE DAM WHICH IS BEING BUILT ACROSS THE MISSISSIPPI

### The Oceanographic Museum of Monaco.

The Oceanographic Museum of Monaco was formally opened on March 29th, 1910, by its founder, Prince Albert I of Monaco, in the presence of representatives of various foreign governments. The celebration included a pyrotechnic exhibition and an allegorical pageant in the beautiful bay of Monaco, a gala performance at the opera and other festivities. The new museum, which is also a laboratory, is connected with the Oceanographic Institute of Paris and both institutions, with an endowment of four million francs ($800 000) have been presented by Prince Albert to the French government in recognition of the hospitality which Paris and France accord to all workers in the field of thought Prince Albert is president of the administrative council of the Institute, which includes among its members ex President Loubet and the physicists Cailletet and Becquerel The direction of the scientific work is confided to an international committee for it was Prince Albert's design to found an institute and a laboratory in which investigators of all nationalities could work together for the advancement of the new science of oceanography The lecture courses of the Institute were inaugurated in 1903, at the Conservatoire des Arts et Métiers. The lectures have since been given in the old building of the Academy of Medicine and at the Sorbonne. The new building of the Oceanographic Institute will soon be completed, and the lectures will be given there after October next

The Oceanographic Museum of Monaco, which has already received the popular name of the Palace of the Sea, is built on the flank of a steep cliff at the edge of the sea. On the water side the building is 256 feet high, while the haight of the main façade on the land side, is 148 feet, the difference being due to tha slope of the cliff The length of the building, parallel to the water front, is 330 feet The cost of construction exceeded $1,500,000 There are only four stories, and the rooms are very high, large, and well lighted The two lower stories which are partly underground, contain the aquariums and laboratories, while tha upper stories are devoted to the exhibition of sounding and other apparatus, and of the rich and varied collections of deep-sea fauna and flora which represent the result of a quarter century of exploration Prince Albert has also placed a small steamer, tha "Elder," at the disposal of the Museum

Almost every year since 1885, the Prince of Monaco has made a scientific cruise in the Mediterranean, Atlantic or Arctic Ocean The experience acquired with the "Hirondelle," a sailing yacht of 200 tons, and afterward with the "Princesse Alice I," an auxiliary three-masted schooner, 170 feet in length, was put to good use in the construction and equipment of tha "Princesse Alice II," with which the later cruises have been conducted This vessel has a steel hull, a length of 240 feet, a breadth of 34 feet, a displacement of 1 400 tons, and a maximum speed of 13 knots. It contains the most improved apparatus for taking soundings and temperatures and collecting specimens of fauna, flora, sand, mud etc, at very great depths. A great part of this apparatus was invented and constructed by the Prince and his assistants.

The cases of the Museum contain representatives of all known deep-sea fauna. Many of these specimens are interesting even to the non-scientific observer because of their strange forms, beautiful colors, and peculiar organs of sight and touch.

These oceanographic explorations and collections also possess great practical value, in addition to their scientific interest. Most edible fishes feed upon the plankton or mass of small animal organisms which are wafted hither and thither by even feeble ocean currents.

The explorations hava proved that the plankton moves in a manner dependent on the season and the locality These migrations appear to be governed by complex laws, the knowledge of which, as it is gradually developed, will be of great value to the fisheries, especially to the steam fisheries, as the fish follow the plankton

In commemoration of tha inauguration of the Oceanographic Museum, the Prince of Monaco has caused a plaque to be struck in gold, silver and bronze. The six gold plaques were presented to tha president of tha French Republic, and the sovereigns of Germany, Italy, Spain, Portugal and Monaco. One hundred plaques in silver and twenty in bronze were distributed among the other invited guests.—L'Illustration

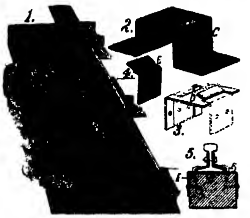
---

The Electrical World remarks that in a report submitted by the chief signal officer of the United States army to tha Secretary of War, it is stated that there are now in the army service a total of [illegible] wireless telegraph stations, of which 13 are in the United States, 9 in Alaska, 5 in the Philippine Islands, 5 on artillery harbor tugs, and 7 in the [illegible] transport service The signal corps has purchased a [illegible] 100,000-cycle alternator for wireless [illegible] service The advisability of the United States adhering to the International Radiotelegraphic Convention, [illegible] is recommended for the consideration of the United States Senate. Wireless [illegible] are now being erected at the Bureau of [illegible] and at the quarters of the signal corps of the army, in Pennsylvania Ave., Washington, to make experiments with the object of selecting the [illegible]

# Patent Department

## IMPROVED RAIL CONNECTION.

To prevent the destructive hammering of the rails when depressed by the passage of a train, a new construction has recently been designed to furnish a more substantial support at the rail joints for them. It



IMPROVED RAIL CONNECTION.

consists in providing timbers or ties running longitudinally under the rails at the joints. In addition to this, a number of very substantial metallic fastenings serve to clamp the rails tightly in position. It is usually the case that the joints of a railroad are arranged to come between and not on the ties and heavy fishplates are depended upon to support them. The construction here illustrated is intended to offer an improvement on such an arrangement of the joints. As shown in the accompanying engraving, the two ties *A*, between which the joint comes, are depressed, and on them is laid the longitudinal timber *B*. The latter is clamped down to the ties by means of a metal fastening *C*, which is shown in full in Fig. 2. This is substantially of U form, and may be termed a "saddle piece." It is preferably mortised into the timber to the depth of its thickness. The base flanges are secured to the ties by means of spikes. Each saddle piece is cut out at the top to form a hook or lip that engages the outer side of the rail base and thus prevents outward movement or spreading of the rails. At the joint the rails are connected by the usual fishplates and bolts and are secured firmly to the timber *B* by means of a metallic fastening *D* such as shown in Fig. 3 and a pair of fastenings *E*, such as shown in Fig. 4. Fig. 5 is a cross-sectional view of the rail joint, and shows how these fastenings are applied. The fastening *D* is approximately L-shaped, and passes under the base of the rails, being formed with a hooked portion, which engages the inner side of the rail base. Over this hook, one of the fastenings *E* is applied, while at the opposite side is another fastening *E*, the fastening *D* being cut away to receive it. Thus a very strong joint is provided, which should reduce the unpleasant hammering noise at the joints and also increase the safety of the railroad. The inventor is Mr. Henry Grass of Alvin, Texas.

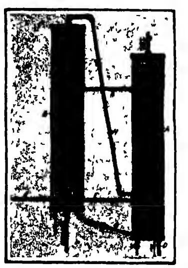
## FENCE POST ANCHOR.

A patent has recently been granted on a novel method of supporting a fence post, so that it will withstand excessive strain. The construction will be especially useful for anchoring corner posts. The device is very simple and inexpensive and may be readily attached to any post. In our illustration, we show in Fig. 1 the construction applied to the ordinary fence post, while in Fig. 2 is shown the construction used for corner posts. In both illustrations the post is designated by the letter *A*. At the bottom of the post is an anchor plate *B*, which at one end is flattened out to form a blade *C*. The opposite end of the anchor plate is doubled upon itself to receive the lower end of a diagonal brace *D*, the upper end of which is bolted to the post. An angle brace *E* is secured to the opposite side of the post and connects it to the anchor plate *B*. The spikes which pass through the anchor plate are long enough to be driven to a considerable depth in the ground, and serve as additional means for preventing the anchor plate from sliding out of position. In use a trench is dug at the point where the post is to be erected. The trench is just wide enough to receive the anchor plate *B*, and the blade *C* of the plate is driven into the undisturbed ground at the end of the trench, thus affording a firm anchorage. Thereafter the post is erected on the anchor plate and the braces *D* and *E* are bolted fast. For corner posts, the anchoring device is used in duplicate. The blades *C* of the anchor plate are driven into the ground at the side, where there will be a lifting strain imposed by the tension of the fence wires. The inventor of this anchoring device for fence posts is Mr. Julius Laux, of Flatonia, Texas.

FENCE POST ANCHOR.

## AMMONIA PURIFIER FOR REFRIGERATING PLANTS.

A recent patent discloses an improved method of purifying ammonia, so as to render it anhydrous in refrigerating plants. The object is to produce a high grade of anhydrous ammonia continuously while the compressor is in operation. An apparatus is provided which is connected in circuit with the compressor and condenser and removes a portion of the heat from the compressed ammonia so as to condense the oil and water vapor and permit dry or partially cooled but uncondensed ammonia to be delivered to the condensing coil. In this way the amount of cooling that

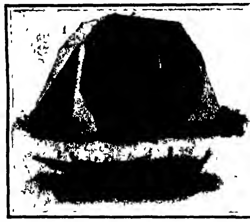


APPARATUS FOR PURIFYING AMMONIA FOR REFRIGERATING SYSTEMS.

is required in the condenser is reduced. The passage of oil to the condenser is prevented and the ammonia is condensed separately, so that only pure anhydrous ammonia is delivered to the expansion valve. The apparatus comprises two holders or drums *A* and *B* which are connected at the bottom by a pipe *C*. The drum *B* is preferably raised above the drum *A*. The compressed ammonia enters the drum *A*, through a pipe *D*, then passes through one or more connecting pipes *E* to the drum *B*, after which it passes out through the pipe *F*. The cooling system consists in a pair of water chambers *G* and a pipe *H*, connecting the top of the water chamber in drum *B* with the bottom of the chamber in the drum *A*. The water passes through the cooling system in the reverse direction to the flow of ammonia through the apparatus. The temperature and rate of flow are so controlled that there will be no condensation of ammonia in the gas holders, but all the oil and water vapor which may be carried along with the ammonia will be condensed in these holders and accumulate in the lower portions. If the valve in the pipe *C* is opened, the oil and water will flow into the bottom of the drum *A* and may be drawn off at that point. The object of letting the pipe from the compressor pass up through the oil and water in the drum *A* is to heat the oil, and thus prevent as far as possible the loss of ammonia. The inventor of this apparatus is Mr. Lawrence Wagner of Missouri Avenue and Missouri Pacific Tracks, Sedalia, Missouri.

## CONVERTIBLE BOAT AND TENT.

For the benefit of campers, hunters, and the like, a folding tent has recently been devised which may be packed into a very small compass and which may also be converted into a canvas boat. Our illustration shows the device in its two forms, partly broken away to reveal the framework. It will be observed that the upper portion of the tent comprises a pair of lazy tongs *A*, connected by cross bars *B*. These are supported on four posts indicated at *C* and *D*, and the structure is rendered quite rigid by means of a system of guy wires. Swung from the framework are a pair of bars *E* which support a hammock *F*. The upper portion of the tent frame is covered with waterproof canvas, and in addition to this, there is a lower canvas section which may be fastened to the upper section by means of buttons, thus forming a spacious tent, and the occupant can sleep on the hammock,



CONVERTIBLE BOAT AND TENT

which is a decided improvement over using the ground for a bed. When breaking camp the posts *C* and *D* are withdrawn from their sockets and the lazy tongs are folded up, so that the entire framework of the tent may be placed in a small bag. To convert this framework into a boat it is extended and inverted, so that the cross bars *B* form the bottom of the boat. The bars *E* of the hammock are hooked to the framework at one end and fastened together at their outer ends to form a bowsprit for the boat. The bowsprit is braced by a pair of arms *H* which are hinged to the cross bar *G*. It will be observed that the lazy tongs at *J* are extended to form oarlocks and the posts *C* of the tent are so constructed as to form oars. The seat of the boat is supported on a pair of longitudinal beams *K*. The canvas top of the tent is applied to the framework, inclosing it and thus forming a flat bottomed canvas boat of large capacity. Mr. Joseph Vaghi of Bethel, Conn., has just secured a patent on this convertible boat and tent.

## INDEX SYSTEM FOR POCKET MEMORANDA.

A patent has recently been granted on an improved pocket memorandum book, which is provided with a novel indexing system. The first leaf of the book is shorter than the others and serves as a topic list, being ruled to allow of entering various topics on which notes are to be kept. The other leaves of the book are cut with series of tabs as shown in the illustration, the tabs on each leaf corresponding in number to the topics provided for in the topic list. When notes on a subject are entered on one of the leaves of the book, all the tabs of this leaf except that opposite the topic to which the notes relate are cut away. When a leaf is filled, it may be removed and filed away in a card index. If it is desired to permit the leaf to remain in the memorandum book after it has been completely filled the tab is partially cut away so that it will still serve to locate the leaf but will not interfere with the thumb in readily finding the next tab underneath in the same series. In this way the entire memorandum book is so arranged that the matter it contains is always properly indexed, and may readily be referred to whenever desired. Furthermore the material is so placed and the leaves are so arranged that when they are removed and filed

MEMORANDUM BOOK WITH NOVEL INDEX SYSTEM

in a card index no transcribing of the notes is necessary The device should be of particular advantage to the modern farmer, horticulturist, gardener, or stock man, who must have some convenient way of collating and preserving the data of his daily work if he is to get a full measure of profit and satisfaction out of his experience from year to year He cannot afford to trust his memory with much important detail, and an elaborate system of keeping a record does not appeal to him The pocket memorandum book with topical index should meet his needs The inventor of this memorandum book is Mr E A. Bagby 1107 Brook Street, Louisville, Ky

## IMPROVED TRACK SANDER.

Pictured in the accompanying engraving is an improved track sander for use with locomotives The apparatus is so arranged that two jets of compressed air are employed, one of which is directed against the sand in the sand box, serving to agitate it, while the other acts to discharge the same continuously and smoothly Special precautions are taken to prevent the nozzles from being clogged with sand In our illustration the sand box is indicated at *A* The sander casing *B* is substantially of Y form It is threaded into the sand box and held in place with a lock nut At the opposite end of the casing is a plug *C*, provided with an extension *D* constituting the nozzle At the extreme inner end of the extension *D* the bore is constricted to form a jet opening, which communicates with a recess in which a ball *F* is placed In addition to this, there is an inclined jet opening *E* At the opposite end of the plug there is a screen *H* which serves to strain the compressed air that enters by way of pipe *J* In the other leg of the
